

DEVELOPMENTAL DISTURBANCES IN SIZE OF TEETH :

MICRODONTIA		Teeth which are smaller than normal.
Types 1. True generalized 2. Microdontia Involving Single tooth 3. Relative Generalized		
True Generalized  All teeth are smaller than normal	Microdontia Involving Single tooth  Only single tooth is smaller, most common seen in maxillary lateral incisor.	
Relative Generalized		Teeth are slightly smaller or normal but the presenting jaw are larger than the normal.
MACRODONTIA		Teeth which are larger than normal
Types 1. True generalized 2. Macrodontia Involving Single tooth 3. Relative Generalized		
True Generalized All teeth are larger than normal	Macrodontia Involving Single tooth  Only single tooth is larger than other teeth.	
Relative Generalized  Teeth are slightly large or normal but presenting jaw are smaller than normal		

DEVELOPMENTAL DISTURBANCES IN NO. OF TEETH :

ANODONTIA		Refers to total lack of tooth development
Types: 1. True Anodontia 2. False Anodontia		
True Anodontia 	 True total involves complete absence of teeth	
True Partial involves one or more teeth		
False Anodontia		It is the result of extraction of all teeth.
SUPERNUMERARY TEETH  It is additional entity to the normal series and is seen in all the quadrants of the jaw. Types : Conical, Tuberculate, Supplemental, Odontome	PREDECIDUOUS DENTITION (Natal Teeth)  It is a hornified epithelial structures without roots occurring on the gingiva over the crest of the ridge which may be easily removed and appear to be erupted at time of birth	
POST PERMANENT DENTITION		Refers to permanent teeth which have been extracted and yet presents subsequently erupted several more teeth, particularly after the insertion of a full denture.

SOFT: Bone is a living and growing tissue. It is specialized, porous and mineralized connective tissue structure.

ALVEOLAR BONE: Defined as the part of maxilla and mandible that supports and forms the socket of the tooth.

ALVEOLAR BONE PROPER

It consists of partly lamellated bone and partly lamella bone.
 (Lamellated bone: It contains lamellae each of which has a blood vessel in a lamellar canal. Some lamellae are arranged parallel to the surface of adjacent bone and others form Haversian canal.
 Lamella bone: It is found applied to that part of inner alveolar wall which gives attachment to the PDL fibers and into which Sharpey's fibers are attached. It is divided into by the secondary fibrils in interstitial substance retrogradually referred as lamellae dura.
 2) Supporting alveolar bone:
 Consist of two parts:
 a) Cortical plate: It is the external compact covering of alveolar process. It is thicker in maxilla than mandible. It is more posterior. It is porous in mandible and dense in maxilla.
 b) Spongy bone: It is the cancellous bone with presence of numerous bone trabeculae, lying between cortical plate and alveolar bone proper. Trabeculae surround marrow spaces and derive nutrition from it. Haversian canal are infrequent.

ALVEOLAR BONE

FUNCTIONS

- 1) Shows the root of tooth
- 2) Anchors the teeth with help of Sharpey's fibers
- 3) Helps to move tooth for better occlusion
- 4) Absorb and distribute occlusal forces
- 5) Supplies the blood to PDL
- 6) Supports and covers eruption of tooth
- 7) Provides and protect processes involving tooth, while supporting primary teeth

ACL CRITERIA:-

- In alveolar wall of tooth:-
- Alveolar sockets appear jagged and uneven.
 - Alveolar process shows bony trabeculae.
 - Alveolar process in edentulous jaws decreases in size.
 - Loss of maxillary bone is accompanied by increase in the size of maxillary sinus.
 - Inverted U-shaped arrangement is more seen, which indicates bone loss.
 - The distance between the crest of alveolar bone and CEJ increases with age approximately by 2.5mm.

CLINICAL CONSEQUENCES

- > "The lamella dura" is the most important diagnostic landmark in determining health of periodontal tissues.
- > Displacement and loss of density is seen by due to fibrosis in periodontal tissue.
- > Bone is resorbed on the side of pressure and resorbed on the side of tension that arise alveolar. It is observed to shift with the tooth.
- > The most harmful change in the alveolar process is associated with periodontal disease. Some loss horizontal or vertical resorption or dehiscence.
- > Diagnosis generally after tooth is lost Bone grafts and implants:-
- Autograft
- Allograft
- Xenograft
- > Max bone graft material (dog bone) is used to substitute bone mass.
- > Involves functional forces & formation of new bone.
- > Bone is functional tissue & loss of bone resorbs.

PERMANENT MAXILLARY SECOND MOLAR

INTRODUCTION

- THE MAXILLARY SECOND MOLAR SUPPLEMENTS THE FIRST MOLAR IN FUNCTION.
- THE DISTOBUCCAL CUSP IS NOT AS LARGE OR AS WELL DEVELOPED, AND THE DISTOBUCCAL CUSP IS SMALLER.

• NO FIFTH CUSP EVIDENT.

BUCCAL ASPECT

- CROWN IS SHORTER CERVICO-OCCLUSALLY AND NARROWER MESIODISTALLY THAN IS THE MAXILLARY FIRST MOLAR.
- THE DISTOBUCCAL CUSP IS SMALLER AND ALLOWS PART OF THE DISTAL MARGINAL RIDGE AND PART OF THE DISTOLINGUAL CUSP TO BE SEEN.
- THE BUCCAL ROOTS ARE ABOUT THE SAME LENGTH, THESE ROOTS ARE MORE NEARLY PARALLEL AND INCLINED DISTALLY.
- DISTOBUCCAL ROOT IS SLIGHTLY DISTAL TO THE DISTAL EXTREMITY OF THE CROWN.
- THE APEX OF THE MESIOBUCCAL ROOT IS ON A LINE WITH THE BUCCAL GROOVE OF THE CROWN.

LINGUAL ASPECT:

- THE DISTOLINGUAL CUSP OF THE CROWN IS SMALLER THAN THE FIRST MOLAR.
- THE DISTOBUCCAL CUSP MAY BE SEEN THROUGH THE SULCUS BETWEEN THE MESIOBUCCAL AND DISTOBUCCAL CUSP.
- THE APEX OF THE LINGUAL ROOT IS IN LINE WITH THE DISTOLINGUAL CUSP TIP INSTEAD OF THE LINGUAL GROOVE AS WAS FOUND ON THE FIRST MOLAR.

MESIAL ASPECT

- THE BUCCOLINGUAL DIMENSION OF THE SECOND MOLAR IS ABOUT THE SAME AS THAT OF THE FIRST MOLAR BUT THE CROWN LENGTH IS LESS.
- THE ROOTS DO NOT SPREAD AS FAR BUCCOLINGUALLY BUT ARE WITHIN CONTOURS OF THE BUCCOLINGUAL CROWN OUTLINE.

DISTAL ASPECT

- BECAUSE THE DISTOBUCCAL CUSP IS SMALLER IN THE MAXILLARY SECOND MOLAR THAN THAT IN THE FIRST MOLAR, MORE OF THE MESIOBUCCAL CUSP MAY BE SEEN FROM THIS ANGLE.
- THE MESIOBUCCAL CUSP CAN NOT BE SEEN.
- THE APEX OF THE LINGUAL ROOT IS IN LINE WITH THE DISTOLINGUAL CUSP.

OCCLUSAL ASPECT

- THE RHOMBOSHAL TYPE OF SECOND MAXILLARY MOLAR IS MOST COMMON, ALTHOUGH IN COMPARISON WITH THE FIRST MOLAR, THE ACUTE ANGLES OF THE RHOMBUS ARE LESS AND THE OBTUSE ANGLES GREATER.
- THE BUCCOLINGUAL DIAMETER OF THE CROWN IS ABOUT EQUAL, BUT MESIODISTAL DIAMETER IS APPROXIMATELY 1MM LESS THAN 1ST MOLAR.
- THE MESIOBUCCAL AND MESIOBUCCAL CUSP ARE JUST AS LARGE AND WELL DEVELOPED AS IN THE FIRST MOLAR, BUT THE DISTOBUCCAL AND DISTOLINGUAL CUSPS ARE SMALLER AND LESS WELL DEVELOPED.
- MORE CONVERGENCE DISTALLY IS SEEN THAN IN THE MAXILLARY FIRST MOLAR.

- FIRST EVIDENCE OF CALCIFICATION : 2.5 YR
- ENAMEL COMPLETED : 7-8 YR
- ERUPTION : 12-13 YR
- ROOT COMPLETED : 14-16 YR

CURVED OCCLUSAL LENGTH OF CROWN (MM)	LENGTH OF ROOT (MM)	MESIODISTAL DIAMETER OF CROWN (MM)	MESIOBUCCAL DIAMETER OF CROWN (MM)	BUCCOLINGUAL DIAMETER OF CROWN (MM)	BUCCOLINGUAL DIAMETER OF CROWN AT CERVIX (MM)
7.0	BUCCAL-13 LINGUAL-12	8.0	7.8	11.8	10.00

PERMANENT MAXILLARY CENTRAL INCISOR

The permanent maxillary incisor are 4 in numbers. The maxillary central incisor is the widest mesiodistally of any of the anterior teeth.

Chronology

First Evidence of Calcification	3-4 months
Enamel Completed	4-5 year
Eruption	7-8 year
Root Completed	10 year

Measurement Table

Cervicoincisal Length of Crown	Length of Root	Mesiodistal Diameter of Crown	Mesiodistal Diameter of Crown at Cervix	Labio-or Buccolingual Diameter of Crown	Labio-or Buccolingual Diameter of Crown at Cervix	Curvature of Cervical Line-Mesial	Curvature of Cervical Line-Distal
10.5 mm	13.0 mm	8.5 mm	7.0 mm	7.0 mm	6.0 mm	3.5 mm	2.5 mm

Labial Aspect

- The mesial outline of the crown is only slightly convex, with the crest of curvature approaching the mesiodistal angle.
- The distal outline of the crown is more convex than the mesial outline; with the crest of curvature higher towards the cervical line.
- The incisal outline is usually regular and straight in a mesiodistal direction after the tooth has been in function long enough to obliterate the mamelons.
- The labial surface is marked by two developmental grooves.

Incisal Aspect

- The labial surface of the crown appears broad and flat in comparison with lingual surface.
- The mesiolabial and distolabial angles are prominent from the incisal aspect.
- The crown of this tooth shows more bulk from the incisal aspect than one would expect from viewing it from the mesial or distal aspect.
- Bilaterally, the outline of the incisal aspect is rather uniform.
- A view of the crown from incisal aspect super imposes it over the root orally so that the root is not visible.

Mesial Aspect

- The crown is wedge-shaped or triangular.
- The mesial ridge of the crown is on a line with the centre of the root. This is special feature of central maxillary incisor.
- The crests of contour gives the crown its greatest Labio-Lingual measurement.
- The cervical curvature is greater on the mesial surface of the tooth than on any other surface.
- The root of this tooth from mesial aspect is cone shaped and the apex of the root is usually blunt.

Lingual Aspect

- Lingual topography gives scoop like form to the crown.
- The lingual outline of maxillary central incisor is reverse of that found on the labial aspect.
- The lingual aspect has convexities and concavities.
- Below the cervical line a smooth convexity is to be found this is called CINGULUM.
- Between the marginal ridges, below cingulum a shallow concavity is present called the LINGUAL FOSSA.

The Root

- The root of the central incisor is cone shaped.
- The apex of the root is bluntly rounded.
- The lingual portion of the root is narrower than the labial portion.
- At the level of the cervical line, the shape of the canal is triangular but becomes circular at the middle level of the tooth.

Distal Aspect

- The crown is thicker towards incisal tip.
- Because of the slope of labial surface labio-lingually, that surface is seen from distal aspect, the creates the illusion of greater thickness.
- The curvature of the cervical line outlining the CEJ is less in extent on the distal than on the mesial surface.

Permanent Mandibular lateral incisor

Introduction

Resembles mandibular central incisor closely thus direct comparison is made with MCI

The 2 incisors i.e. central & lateral operate in the dental arch as a team.

Thus their functional form is related. Compared to MCI the shape of ML2 is uniform. Rarely will it have a labial & lingual root division in the cervical 2°.

ML2 is somewhat larger but generally speaking, its form closely resembles the MCI. Also called second incisors.

LABIAL ASPECT:-

The lateral incisor looks like the central incisor in overall appearance but is slightly larger and are bilaterally symmetric. Whereas the central incisor has a broad mesial edge, the mesial edge of the lateral inclines toward the distal and forms a rounded mesial angle with the distal side. The distal side is slightly convex. The mesial mesial angle is sharp, the mesial side can be straight or slightly convex as it tapers toward the cervical line. Both the mesial and distal contact areas are in the mesial angle. The cervical line forms a narrow arch. The root is straight, tapering in the apical third.

Lingual aspect

The characteristics of this surface are:-

An outline that is the reverse of the labial side.

Cuspids, lines and ridges that appear the same as those on the central incisor.

Except for size and length, the mandibular lateral incisor is similar to the central incisor and has the same characteristics.

However, the linguals is directly duplicated as it tends to curve toward the center.

Table 1.1
Mandibular Lateral Incisor

Sex		Age		Height		Weight		Crown Length		Crown Width		Crown Area		Crown Volume	
Male	Female	10-12	13-15	16-18	19-21	22-24	25-27	10-12	13-15	16-18	19-21	22-24	25-27	10-12	13-15
3.7	3.6	3.3	3.1	2.9	2.7	2.5	2.3	1.0	1.1	1.2	1.3	1.4	1.5	1.6	1.7

Proximal aspect:-

The mesial side of the crown is often longer than the distal side causing the incisal ridge to slope downward in a distal direction. The distal contact area is more toward the cervical than the mesial contact area.

Except for size, no marked difference is between the mesial & distal surfaces.

Even the curvatures of cervical line are similar in extent. A tendency exists toward a deeper concavity immediately above the cervical line on the distal surface.

Root form is similar to that of the central incisor.

Incisal aspect

The incisal edge of the lateral incisor curves toward the distal, following the contour of the mandibular arch.

Whereas the mesial edge of the central incisor is straight.

The curvature on the lateral incisor creates a distally displaced cuspids in comparison to the centrally placed cuspids of the central incisor.

This strategy assists in distinguishing the two teeth from each other.

ROOT:

- Root is wider, thicker, little longer.
- Longitudinal grooves are more common.
- Variation of root is common.

ORAL EXFOLIATIVE CYTOLOGY

Definition : It is Study of Cells Exfoliated from the Oral Cavity

Recommended for

1. Detection of Malignant Cells.
2. Detection of Precancerous Cervical Lesions In Women.
3. Assessment of female hormonal status in case of infertility and endocrine disorders.
4. Detection of Genetic Sex.
5. Detection of The Presence of Infectious Micro organisms.

INSTRUMENTATIONS

- Glass Microscope slides
- Glass marking pencil
- Cotton No applicator or swabber applicator
- Fixative
- Cold water - Pickering's glass
- 70% Alcohol
- Cover glass
- DPK mounting media

Area		
Size		
Use		

Method

- First Collect The Smears And Make From The Lesion
- This Can Be Done With The Help Of Volar Contact Specula
- Washed Tongue Blade and Cytol brush
- This Collected Material Quickly Spread Evenly Over Microscopic Slide
- Fix Instantly Before Dry
- Washed brush in Spray Cytol 95% Alcohol, Squid Part Of Alcohol and Water
- It Should Be Allow To Stand For 30 Min In Air Dry

Smear Usually Divided Into 5 Classes

- Class I (Normal) - Dry, No Keratin, No Squames
- Class II (Atypical) - indicates presence of Atypical flat Keratin Changes
- Class III (Intermediate) - This is An In Between Cytology That Separates Cancer From Non Cancer Diagnosis
- Class IV (Suggested as Cancer) - This cell With In Malignant Characteristic and Many Cells With Border Line Characteristics
- Class V (Positive For Cancer) - They are Obviously Malignant

Staining Method in Cytology

- Papanicolaou Staining Method
- Rapid Papanicolaou Staining
- Hematoxylin and Eosin Staining Method
- Method Gramwell Gramson Staining Method
- Most Rapidly Used Method is Papanicolaou Method

PAPANICOLAOU METHOD (PAP)

- Steps of Staining Procedure
1. Fixative - 95% Ethyl Alcohol
 2. Nuclear Staining - By Using Hematoxylin Basic Acid Alcohol or 0.5% Acetone Solution of HCL Fast Blue
 3. Cytoplasmic Staining - Toluidin Blue 2.5% And EA 10
 4. Dehydration - Run The Smear In Absolute Alcohol
 5. Clearing - Alcohol Is Being Replaced By Xylene
 6. Mounting of Slide - Mounting Media with Clearing Agent Prevent Fading of The Slide.

Appearance of cells in relation to location :

- (Location is important)
1. Lip - Mature cells
 2. Hard palate - High degree of keratinization and some cells are anucleate
 3. Gingiva & Buccal Tongue - Intermediate nature by composed of varying percentage of anucleate & nucleated squamous cells
 4. Buccal and Labial Floor of mouth, anterior tongue, soft palate & oropharynx - Less mature by predominantly squamous cells

NORMAL APPEARANCE OF ORAL EPITHELIAL CELLS

Hard palate - High degree of keratinization and some cells are anucleate

Palate - Anucleated and some nucleated squames, characterize the smears from this area.

Gingiva - Intermediate nature by composed of varying percentage of anucleate & nucleated squamous cells

Gingiva : There is a mixture of anucleate and nucleated squames. The nuclei show progressive stages of pyknosis and degeneration. The cytoplasm range from orange to eosinophilic. The cells are irregular and occasionally folded

It is Useful In Diagnosis of

- Herpes Simplex, Herpes Zoster
- Pemphigus Vulgaris, Benign Familial Pemphigus
- Keratosis Follicularis
- Hereditary Benign Intraepithelial Dyskeratosis
- White Sponge Nevus
- Pernicious and Sickle Cell Anemia

3rd Year (2011-12)

DEVELOPMENTAL DISTURBANCES IN SHAPE OF TEETH :

GEMINATION

The anomalies which arise from an attempt at division of single tooth germ by an invagination with resultant incomplete formation of two teeth.

FUSION

The union of two normally separated tooth buds with the resultant formation of a joined tooth with confluence of dentin.

CONCRESCENCE

The union of two teeth by cementum without confluence of the dentin.

DILACERATION

It is an abnormal angulation or bend in the root.

TALON CUSP

It is an anomalous structure resembling an eagle's talon, projects lingually from the gingulum area of a maxillary or mandibular permanent incisor.

DENS IN DENTE

Deep surface invagination of the crown or root that is lined by enamel.

DENS EVAGINATUS

Cusp like elevation of enamel located in the central groove or lingual ridge of permanent premolar or molar teeth.

TAURODONTISM

It is a peculiar dental anomaly in which the body of tooth is enlarged at the expense of the roots.

SUPERNUMERARY ROOTS

Refers to the development of an increased number of roots on a tooth compared with that classically described in dental anatomy.

Oral Mucous Membrane : Keratinized and Non Keratinized Epithelium

The moist lining of GIT, nasal passage and other body cavities that communicates with exterior is known as Mucous Membrane. Mucous membrane that lines the oral cavity is known as Oral Mucous Membrane.

OMM is classified on the basis of - a) LOCATION b) FUNCTION c) KERATINISATION

CMM (KERATINIZED) - 1) KERATINIZED - a) ORTHO & b) PARA 2) NON-KERATINIZED

The KERATINISED EPITHELIUM has various cell layers - 1) STRATUM BASALE 2) STRATUM SPINOSUM 3) STRATUM GRANULOSUM 4) STRATUM CORNEUM

STRATUM BASALE

- The layers are named from their morphologic appearance.
- Single cell is at apex of each layer.
- After reaching, cell may remain in basal layer or may migrate upward.
- After reaching the surface, it sheds off - DESQUAMATION.
- TURN OVER TIME - Time taken for the cell to divide and pass through entire epithelium.
- Process of cell migration from basal layer to surface is called MATURATION.
- The stratum basale is a single layer of cuboidal cells present above basement membrane.
- The cell layer consists of progenitor & maturing cell population which appear same morphologically.
- Basal and parabasal epinuous cell layer is known as STRATUM GERMINATIVUM.
- 2 cell populations are present - 1) SERRATED - heavily packed with tonofilaments which are adaptation for attachment. 2) NON-SERRATED - composed of slowly cycling stem cells.
- Certain transmembranous proteins are also present - DESMOGLEIN & DESMOCELLIN.

STRATUM SPINOSUM (PRICKLED CELL LAYER)

- It is a 12-22 layer of polyhedral cells.
- On light microscopy, it appears that cells are joined by intercellular bridges.
- Tonofilaments course from cell to cell across these bridges.
- Tonofilament & desmosomes give tensile strength.
- Shrinkage of cells during histologic preparation & desmosomes attachments together are responsible for prickled appearance (ACANTHOSIS).
- FUNCTION - Synthesis of proteins more active than other layers.

STRATUM CORNEUM

- Composed of flat dehydrated cells (squamous).
- Cells only have tonofilaments surrounded by filagrin and are anucleated.
- Keratinisation or absence of nucleus is called ORTHO KERATINISATION.
- If cell retain shrunken/ pyknotic nucleus then it is termed as PARAKERATINISATION.

STRATUM GRANULOSUM

- This layer consists of flatter & wider cells above prickle cell layer.
- It is named for eosinophilic keratohyaline granules.
- ODLAND BODY / KERATINOSOME / MEMBRANE COATED GRANULES forms its upper spinous layer and in granular layer.
- These are glycolipids.

Non-keratinising epithelia differ from keratinising epithelia primarily because they do not produce a cornified surface layer.

The NON-KERATINISED EPITHELIUM consists of 3 layers - 1) STRATUM BASALE 2) STRATUM INTERMEDIUM 3) STRATUM SUPERFICIALE

STRATUM BASALE

- It is a single layer of cuboidal cells.
- It is a site of cell division.
- It is made of 2 different types of cells - PROGENITOR & MATURING CELL.
- Tonofilaments are present.

STRATUM INTERMEDIUM

- Cells of stratum intermedium are larger than spinous layer.
- It is several cell thick.
- Tonofilaments are dispersed & thick.
- Cells are larger, round & plump or with few and less organized tonofilaments.
- DELAND BODIES appear in upper part of this layer (Dense, circular with amorphous keratin-lamellae), but no prickly appearance.
- These granules may have similar function but contents have different lipid composition & do not form an effective permeability barrier.

STRATUM SUPERFICIALE / STRATUM DISTENDUM

- It contains nucleated cells.
- Lack keratohyaline granules.
- It reflects mechanical flexibility.
- There are more number of flattened cells.
- Cells aren't dehydrated thus form a surface that is flexible and tolerant to compression & distention.

Permanent Maxillary 1st Premolar

Introduction

- Premolars are anterior to the molars in the permanent dentition.
- They are total 8 in number; 2 in each quadrant.

- They are mainly used for grinding purpose.
- The buccolingual dimension of the crown is greater than the mesiodistal dimension.

Buccal Aspect

- Mesial outline of the crown is slightly concave from the cervical line to the mesial contact area.
- Distal outline of the crown below the cervical line is straighter as compared to mesial outline.
- Mesial slope of the buccal cusp is rather straight and longer than distal slope.

Chronology

- First evidence of calcification: 1.5 to 2.0 yrs
- Enamel completed: 5 to 6 yrs
- Eruption: 10 to 11 yrs
- Root completed: 12 to 13 yrs

Occlusal Aspect

- Roughly hexagonal and wider on the buccal than on the lingual.

Root

- The roots are 3 or 4 mm shorter than those of maxillary canine.

Mesial Aspect

- The mesial aspect of the crown of the maxillary first premolars is roughly trapezoidal.
- There is a marked depression called mesial developmental depression.
- Mesial marginal developmental groove is continuous with the cervix of groove of occlusal surface and crossing the marginal ridge.

Lingual Aspect

- The crown tapers towards the lingual because the lingual cusp is narrower mesiodistally than the buccal cusp.
- Lingual cusp is shorter than buccal cusp so the mesial and distal slopes and cusp tip of buccal cusp may be seen from the lingual aspect.

Distal Aspect

- It is similar to mesial aspect.
- A deep developmental groove crossing the distal marginal ridge of the crown is not evident.
- The curvature of the cervical line is less on the distal than on the mesial surface.

	Cervico-occlusal length of crown	Length of root	Mesio-distal diameter of crown	Mesiodistal diameter of crown at cervix	Labio-lingual diameter of crown	Labio-lingual diameter of crown cervix	Curvature of cervical line - mesial	Curvature of cervical line - distal
premolars	8.5	14.0	7.0	5.0	9.0	8.0	1.0	0.0

SELF-DETECTION OF ORAL CANCER

IN ITS VERY EARLY STAGES, MOUTH CANCERS CAN BE EASILY IGNORED.

YOU CAN IMPROVE YOUR CHANCES OF SURVIVAL IF THE CANCER IS DETECTED EARLY AND TREATED RAPIDLY

A PATIENT SHOULD CHECK FOR

- A SORE IN THE MOUTH THAT DOES NOT HEAL WITHIN THREE WEEKS.
- A LUMP OR OVERGROWTH OF TISSUE ANY WHERE IN THE MOUTH.
- A WHITE OR RED PATCH ON THE GUMS, TONGUE, OR LINING OF THE MOUTH.
- A FEELING THAT SOMETHING IS CAUGHT IN THE THROAT.
- A CHRONIC SORE THROAT OR HOARSE VOICE THAT PERSISTS EVEN AFTER CONSERVATIVE TREATMENT MEASURES.
- DIFFICULTY IN CHEWING OR SWALLOWING.
- DIFFICULTY IN MOVING THE JAW OR TONGUE.
- HUMBNESS OF THE TONGUE OR OTHER AREAS OF THE MOUTH.
- SWELLING OF THE JAW THAT CAUSES THE DENTURES TO FIT POORLY OR BECOME UNCOMFORTABLE.

LUMP BEHIND MOLARS

ULCER ON TONGUE

BUCCAL MUCOSA

SWELLINGS

DIFFICULTY IN OPENING MOUTH

WHITE PATCH

HARD PALATE

LIP-CANCER

(STEPS FOR SELF DETECTION OF ORAL CANCER)

Neck
(head upright)
With your head upright try to feel both sides of your neck, and under your jaw.

Neck
(head back)
With your head tilted back, look for masses or lumps.

Lips
Perioral and Intraoral Soft Tissue Examination.

Gums
With your lips pulled away examine all the gums.

Cheeks
Put your cheek only for your teeth and observe.

Palate
Open wide to see the back and roof of your mouth.

Tongue
Grab the End of your tongue with a tissue or glove. Pull your tongue out, right and left and examine each surface.

Tongue
(upward)
Raise the tip of your tongue to the roof of your mouth. Check the floor of your mouth and under your tongue.

Floor of the mouth
(perioral and intraoral soft tissue examination)

Oropharynx
(perioral and intraoral soft tissue examination)

VESICULOBULLOUS LESIONS

DEFINITION:

Vesicle is a small 2-5 mm circumscribed elevated lesion on the skin or mucous membrane composed of thin or thick surface covering overlying or containing accumulation of fluid which may be clear or slightly red i.e. serum plasma or blood. It may be either subepithelial or intraepithelial.

Bulla is a large vesicular type lesion which is of more than 5mm in size. It may develop directly or may form from the union of several vesicles erupting close together.

CLASSIFICATION:

Oral lesions:

1. Primary herpetic gingivostomatitis
2. Secondary herpes simplex infection
3. Herpes zoster
4. Herpangina
5. Small pox
6. Chicken pox
7. Mumps
8. HIV
9. Measles

Herpes Simplex

1. Primary herpetic stomatitis

Primary Herpetic Stomatitis

Clinical Features:

- Affects children and young adults.
- Multiple painful oral ulcers preceded by vesicles.
- It is characterized by fever, irritability, headache, pain upon swallowing and regional lymphadenopathy.
- After few days, mouth becomes painful and gingiva gets inflamed and erythematous.
- Siles, lips, tongue, buccal mucosa, palate, pharynx and tonsils.
- Yellowish fluid filled vesicles develop. They rupture and form shallow, extremely painful ulcer covered by grey membrane and surrounded by erythematous halo.
- It heals spontaneously within 7-14 days and leaves no scar.

Histologic Features:

- Herpetic vesicle is an intraepithelial blister filled with fluid.
- Infected cells are swollen and have pale eosinophilic cytoplasm and large vesicular nuclei known as **BALLOONING DEGENERATION**.
- Others contain intranuclear inclusions known as **LIPSCHUTZ BODIES**.
- Cytoplasm of the infected cells form giant cells.

Secondary Herpetic Stomatitis

Etiology:

- Reactivation of latent herpes simplex virus type 1.
- Triggers: sunlight, stress, immunosuppression reactivation common.

Clinical Features:

- Usually seen in adult patients.
- Burning or tingling sensation, feeling of tightness, swelling or slight soreness is seen at the location in which the vesicles subsequently develop.
- Gray or white vesicles rupture quickly leaving a small red ulceration sometimes with a slight erythematous halo.
- The most common sites are hard palate and attached gingiva or alveolar ridge.
- It heals within 7-10 days.

Histological Features:

- Ballooning degeneration.
- Lipschultz bodies.
- Multinucleated giant cell.

Skin lesion:

1. Pemphigus
2. Erythema multiforme
3. Epidermal bullosa
4. Bullous lichen planus
5. Lupus erythematosus
6. Pemphigod

2. Secondary herpetic stomatitis

HERPES ZOSTER

- It is an acute infectious viral disease extremely painful in nature characterized by inflammation of dorsal root ganglia or extramedullary cranial nerve ganglia associated with vesicular eruptions of the skin or mucous membrane supplied by affected sensory nerves.
- It is caused by reactivation of the latent v-z virus which had been acquired during previous attack of chicken pox.

Clinical Features

- Patient exhibits fever, a general malaise and pain and tenderness usually unilateral.
- Within few days, the patient has a vesicular eruption of skin or mucosa supplied by affected nerves.
- Triggering factors: trauma, development of malignancy or tumour involvement of dorsal root ganglia.
- Common in immunocompromised patients.
- It involves the face by infection of trigeminal nerve; usually consist of unilateral involvement of skin areas supplied by either ophthalmic maxillary or mandibular nerves.
- The characteristic feature is unilaterality of the lesions.

Histologic features

- Microscopically, virus infected epithelial cells show homogenous nuclei representing viral products with margination of chromatin along the nuclear membrane.
- Multinucleation of infected cells is also typical.
- Acantholytic vesicles eventually breakdown and ulcerate.

PEMPHIGUS

It is serious chronic skin disease characterized by the appearance of vesicles and bullae, small or large fluid filled blisters that develop in cycles. There are three primary subsets of pemphigus.

1. Pemphigus vulgaris
2. Pemphigus foliaceus
3. Paraneoplastic pemphigus

PEMPHIGUS VULGARIS

It is an autoimmune, intraepithelial blistering disease affecting the skin and mucous membranes. It results from a breakdown or loss of intercellular adhesion, thus producing epithelial cell separation known as acantholysis.

Clinical Features

- Characterized by rapid appearance of vesicles and bullae varying in diameter from few mm to cm. The lesion contain thin watery fluid shortly after development but may soon become purulent or sanguineous.
- The loss of epithelium occasioned by rubbing apparently unaffected skin is termed **NIKOLSKY'S SIGN** which is caused by prevesicular edema which disrupts the dermal-epithelial junction.

Histologic Features

- Vesicle or bulla is formed entirely intraepithelially just above the basal layer producing the distinctive **SUPRABASILAR SPLIT**.
- Intercellular bridges between the epithelial cells disappear which results in loss of cohesiveness or acantholysis and clumps of epithelial cells are often found lying free within the vesicular space. These are called **TZANCK CELLS**.
- They are characterized by degenerative changes which includes swelling of nuclei and hyperchromatic staining.

DENTAL PULP

Dental pulp can be defined as a richly vascular and innervated connective tissue of mesodermal origin enclosed by dentin, it occupies the center of each tooth.

ANATOMY OF PULP

- ✓ **Coronal pulp** - The coronal pulp has shape according to the outer surface of crown. It has pulp horns, which are protrusions that extend into the cusps of each crown.
- ✓ **Radicular pulp** - The radicular pulp extends from the cervical region of the crown to the root apex. The radicular portion of the pulp is continuous with the periapical connective tissue through the apical foramen or foramina.
- ✓ **Accessory canals** - The accessory canals leads from the radicular pulp laterally through the root, it communicate between radicular pulp and periodontal tissue.
- ✓ **Apical foramen** - The opening of pulp cavity at the apex is constricted and is called apical foramen.

ZONES OF THE PULP

- 1. Odontoblastic zone** - Lines the outer pulpal wall and consists of the cell bodies of odontoblasts and lie in a continuous row near dentinal end of the pulp.
- 2. Cell free zone** - zone of well, sub odontoblastic layer. Lies just beneath the odontoblastic zone. Prominent in coronal pulp. Fibers are present.
- 3. Cell rich zone** - It is situated just below the cell free zone. Consists of fibroblast, undifferentiated mesenchymal cells, macrophages, immunocompetent cell and young collagen fibers.
- 4. Pulp core** - Located in the center of the coronal and radicular pulp. Contains large nerves and blood vessels.

CELLS OF PULP

- ✓ **Fibroblasts** - Fibroblasts are the most numerous cell type in pulp. Helps in synthesis, maintenance and degradation of pulp matrix.
- ✓ **Odontoblast** - Second most prominent cell in pulp. They are tall, columnar in crown, cuboidal in middle of the root, flat, spindle shaped near the apex of tooth.
- ✓ **Undifferentiated mesenchymal cells** - Polyhedral in shape with peripheral processes and large oval nucleus. They are totipotent cell and give rise to odontoblast, fibroblast and macrophages.
- ✓ **Defense cells** :
 - ✓ **Macrophages** - Scavenger cell, help in elimination of dead cells.
 - ✓ **Dendritic cells** - Capture and present foreign antigen to T cells.
 - ✓ **Mast cell** - They release heparin and histamine in response to injury or inflammation of bodily tissues.
 - ✓ **Plasma cell** - They are responsible for production of antibodies.

MATRIX

- ✓ **Fibers** - Prominent collagen type I & III present.
- ✓ **Ground substance** - Mucopolysaccharide, Glycosaminoglycans, Proteoglycans.
- ✓ **Blood vessels** - Blood vessels enter and exit the dental pulp by way of apical and accessory foramina. They divide and subdivide within pulp to form an extensive vascular capillary network.
- ✓ **Lymphatics** - Anterior teeth drains to submental lymph nodes. Posterior teeth drains to submandibular and deep cervical lymph nodes.
- ✓ **Nerves** - The nerves form a plexus just below the odontoblastic zone known as "PLEXUS OF RASCHKOW".

FUNCTIONS

- ◆ Inductive
- ◆ Formative
- ◆ Nutritive
- ◆ Protective
- ◆ Defensive or reparative

Odontoblast

Fibroblast

Dendritic cell

Plasma cell

Mast cell

Macrophage

PULP CALCIFICATIONS

- It is a pathologic process characterized by localized / generalized calcification within the pulp.
- ✓ **True pulp stone** - Localized masses of calcified tissue having tubular structure.
- ✓ **False pulp stone** - Localized masses of calcified tissue not having tubular structure but made of concentric layers of calcium deposited around a central nidus.
- ✓ **Diffuse calcifications** - Linear strands or columns of calcification paralleling the blood vessels & nerves of the pulp.
- A is Embedded pulp stone, B and C are Free pulp stone

DEVELOPMENTAL DISTURBANCES OF TONGUE

THEY ARE AS FOLLOW:-

1. MICROGLOSSIA
2. ANKYLOGLOSSIA
3. MACROGLOSSIA
4. FISSURED TONGUE

5. MEDIAN RHOMBOID GLOSSITIS
6. BENIGN MIGRATORY GLOSSITIS
7. CLEFT TONGUE

8. HAIRY TONGUE
9. LINGUAL VARICES
10. LINGUAL THYROID NODULE

MICROGLOSSIA

A Rudimentary, small tongue.

CAUSE:- Lack of muscular stimulus b/w the alveolar arches.

CLEFT TONGUE (BIFID TONGUE)

-Appear as deep groove in the midline of the dorsal surface.

CAUSE:-

-Lack of merging of the lateral lingual swelling of the tongue.

ANKYLOGLOSSIA (TONGUE TIE)

IT Occurs when the inferior frenulum attaches to the bottom of the tongue.

COMPLICATION:-

- Speech problem specially in sound like l,r,t,d,n,th,sh,z.
- Feeding problem in infant.
- Persistent gap b/w mandibular incisors.

MEDIAN RHOMBOID GLOSSITIS

-Posterior dorsal point of fusion of lingual tubercles occasionally defective leaving a rhomboid shape smooth arhythmatous mucosa lacking in taste- burds or papillae.

CLINICAL FEATURES:-

Midline soft palate erythma in the area of routine contact with underlying tongue involvement called "KISSING LESION".

HISTOLOGIC FEATURES:-

- Smooth/nodular surface covered by atrophic stratified squamous epithelium with fibrous stroma & dilated capillaries.
- Elongation of rete process.
- Inflammatory cell infiltrate.

MACROGLOSSIA (TONGUE HYPERTROPHY)

Means large tongue.

- TYPES:-** 1. true macroglossia
2. pseudo macroglossia.

Associated with 'DOWNSYNDROME' "BECKWITH WIEDEMANN SYNDROME".

BENIGN MIGRATORY GLOSSITIS

(GEOGRAPHIC TONGUE)

-Is a psoriasisform mucositis of tongue.

HISTOLOGIC FEATURES:-

- A prominent serpiginous lines at the periphery of depapillated patch.

FISSURED TONGUE (SCROTAL TONGUE)

-Appear as grooves on dorsal & lateral aspect of tongue of varying depth.

-Associated with "MELKER-SSON ROSENTHAL" & "DOWN" Syndrome.

HISTOLOGIC FEATURES

- Increased thickness of lamina propria.
- Loss of filiform papillae.
- Hyperplasia of rete pegs.
- Neutrophilic microabscess within the epithelium.
- Mixed inflammatory infiltrate in lamina propria.

HAIRY TONGUE

-Defective desquamation of filiform papillae.

CAUSE:-

- Hypertrophy of filiform papillae due to lack of mechanical stimulation & debridement.
- Poor oral hygiene.

CLINICAL FEATURES:-

- Burning tongue.
- Halitosis.
- Tickling & Gagging sensation.

HISTOLOGIC FEATURES:-

- Elongation of filiform papillae.
- Inflammator cell infiltrate.

LINGUAL VARICES

-A dilated, tortuous vein appear as a red-purple shotlike clusters of vessels on ventral surface or lateral border of tongue.

LINGUAL THYROID NODULE

-Condition in which follicles of thyroid tissue are found in substance of tongue.

DIVISION INTO THIRDS

For purposes of description, the crowns and roots of teeth have been divided into thirds.

The surfaces of the crown and root portions are divided into thirds, which are named according to their locations.

Crown may be divided into thirds on the basis of directions as follows:

- ◊ Incisive or Occlusocervically
- ◊ Mesiodistally
- ◊ Labial or Buccolingually

Incisive or occlusocervically, it is divided into:

Mesiodistally it is divided into:

Labial or buccolingually it is divided into:

Division of root into thirds

The root is divided into thirds as follows:

LINE ANGLES

A line angle is formed by the junction of two surfaces and derives its name from the combination of the two surfaces that join to form the line angle.

Line angles of anterior tooth

There are total 6 line angles in anterior teeth.

Line angles of posterior tooth

There are total 8 line angles in posterior teeth.

Guided by

Prof. and H.O.D. Dr. Bineta Trivedi
Reader Dr. Sachin Shah
Sr. Lec. Dr. Rajesh Patel
Lec. Dr. Anil Patel and Dr. Manojkumar Shrivastava

POINT ANGLES

A point angle is formed by the junction of three surfaces and derives its name from the combination of the surfaces that join to form the point angle.

Point angles of anterior tooth

There are total 4 point angles in posterior teeth.

Point angles of posterior tooth

There are total 4 point angles in anterior teeth.

SALIVARY GLAND TUMOURS

BENIGN TUMORS

Pleomorphic adenoma (Mixed tumor)

Most common benign salivary tumor. It is a mixed tumor consisting of epithelial and mesenchymal components.

It is a slow growing tumor and is usually found in the parotid gland. It is a benign tumor and is usually found in the parotid gland.

Clinical features:

- Painless growth in the mixed salivary gland.
- Proliferates but may show some regression.
- Slow growing, firm mass.
- Female predilection - 60-70% of cases.
- In recurrent tumors, the capsule may be present in front of the tumor.

- Consists of islands of pleomorphic epithelium and mesenchymal fibrous tissue.
- Myxomatous cells are most numerous.
- The epithelium may form cystic structures or may occur in islands or nests or surrounding cords or sheets of cells.
- Fibrous connective tissue encloses the tumor, but may give a broad capsule.

Warthins tumor (Papillary Cystadenoma Lymphomatousum)

• Benign neoplasm that occurs almost exclusively in parotid glands. Second most common salivary gland tumor.

Clinical features:

- Slow growing, painless.
- Most commonly occurs in the tail of parotid, near angle of mandible. Usually occurs bilaterally.

Histopathology:

- Made up of two histologic components: epithelial and lymphoid tissue.
- It is usually an adenoma containing cyst formation, with papillary projections into the cyst spaces and a lymphoid reaction showing germinal centers.
- Outer layer cells are tall columnar with centrally placed hyperchromatic nuclei and a long granular and eosinophilic cytoplasm.
- Outer layer cells are usually arranged in strands.
- Multiple papillary folds of epithelium bring into cystic spaces.

Warthin's tumor
Tall columnar double layer epithelium lining spaces, lymphoid stroma.

MALIGNANT TUMORS

Acinic cell carcinoma

It is the third most common malignant salivary gland neoplasm, after mucoepidermoid carcinoma and adenocarcinoma.

Clinical features:

- Painless growth in the mixed salivary gland.
- Most common malignant salivary gland tumor in children.
- Proliferates but may show some regression.
- Slow growing, firm mass.
- Female predilection - 60-70% of cases.
- In recurrent tumors, the capsule may be present in front of the tumor.

Histological features:

- Exhibits four growth patterns: solid, papillary, cystic, tubular, cords, cords.
- The most characteristic cell seen has the features of the acinar cells, with abundant granular basophilic cytoplasm and a vesicular nucleus.
- Other cells are seen are the transitional duct cells which are smaller and the vesicular cells, which are seen to be unique of this tumor.

Acinic cell carcinoma showing sheets of granular basophilic cells across outer rim.

Mucoepidermoid carcinoma

• Most common malignant neoplasm of both major and minor salivary glands.

• Parotid is the most common site.

Clinical Features:

- Most common malignant salivary gland tumor in children.
- The low grade tumors are slowly enlarging, painless masses, which resemble the pleomorphic adenoma.
- The high grade tumors grow rapidly and produce pain as an early symptom. Facial nerve palsy is common when parotid is involved.

Histopathology:

- Composed of mucous secreting cells, epidermoid type (squamous cells) and intermediate cells.
- The mucous cells are of cuboidal, strap and cord formation.
- The epidermoid cells are polygonal shaped with prominent intermediate filigree and early keratinization.
- A group of highly anaplastic keratinocytes related to its intermediate cells.

Mucoepidermoid carcinoma

Adenoid cystic carcinoma (cylindroma)

• Slow growing but aggressive neoplasm.

Clinical features:

- Painless, subcutaneous and accessory glands in the palate and tongue are the most commonly involved glands.
- Early local pain, facial nerve palsy, fixation to deeper structures and local invasion are some of the presenting features.

Histological features:

- 3 growth patterns:
 - Cribriform pattern shows basophilic epithelial cells nests that form multiple cylindrical cyst like pattern resembling a Swiss cheese or honey comb pattern.
 - Tubular pattern: tubular structures are lined by stratified cuboidal epithelium.
 - Solid pattern: shows solid groups of cuboidal cells with little tendency towards duct or cyst formation.

Polymorphous low grade adenocarcinoma (PLGA)

- Limited to minor salivary gland sites.
- Characterized by bland, epithelial nests, strands, infiltrative growth and perineural infiltration.

Clinical features:

- Typically presents as a firm, non tender swelling involving the buccula of the cheek, palate or upper lip.

Histological features:

- Four types of growth patterns are seen: solid, ductal, cystic and tubular.
- Sometimes a cribriform pattern is seen, which resembles that of cystic carcinoma.
- Tumor is composed of cuboidal to columnar cells that have undergone to spindle shaped nuclei.

PSEUDOCYSTS

An abnormal or dilated cavity resembling a true cyst but not lined with epithelium is known as Pseudocyst .

ANEURYSMAL BONE CYST	SIMPLE BONE CYST/ TRAUMATIC BONE CYST/ HEMORRHAGIC BONE CYST/ UNICAMERAL BONE CYST	STATIC BONE CYST / STAFNE'S BONE CYST / LATENT BONE CYST	MUCOUS EXTRAVASATION CYST
<p>An intrasosseous accumulation of variable sized, blood filled spaces surrounded by the cellular fibrous connective tissue that often is admixed with trabeculae of reactive woven bone.</p> <p>May occur due to local circulatory disturbances, or maldevelopment of blood vessels</p>	<ul style="list-style-type: none"> A benign pathologic cavity in bone that is not lined with epithelium. May be associated with trauma. 	<ul style="list-style-type: none"> It represents a focal concavity of the cortical bone on lingual surface of the mandible. It is a developmental defect which contains a portion of sublingual / submandibular salivary gland within the body of the mandible. 	<ul style="list-style-type: none"> Extravasation mucocele results from a broken salivary gland duct and consequent spillage into the soft tissue around this gland
<p>CLINICAL FEATURES :</p> <ul style="list-style-type: none"> Age: 20-30 years Site: Mandibular predominance, mostly posterior region Firm, diffuse, rapidly growing swelling with facial asymmetry. Pain, paresthesia, compressibility, crepitus. 	<p>CLINICAL FEATURES:</p> <ul style="list-style-type: none"> Age: 10-20 years Male:female = 2:1 Site: Mandibular premolar and molar region, maxillary molar. Painless swelling of affected area. paresthesia, bone expansion in some cases. 	<p>CLINICAL FEATURES:</p> <ul style="list-style-type: none"> Age: Middle aged Male predominance Site: Below the mandibular canal in the posterior mandible between molar and angle of mandible Does not increase in size thus known as static bone cyst 	<p>CLINICAL FEATURES :</p> <ul style="list-style-type: none"> Age: Young adults and children Site: Lower lip Size: 1-2 cm Dome shaped, fluctuant swelling. Superficial lesion appear as bluish translucent hue but deeper lesion may appear normal in color.
<p>RADIOGRAPHIC FEATURES:</p> <ul style="list-style-type: none"> Unilocular / multilocular radiolucency Ballooning or blow out distention of bony contour. Honey comb or soap bubble like appearance 	<p>RADIOGRAPHIC FEATURES:</p> <ul style="list-style-type: none"> Unilocular/multilocular well defined radiolucency (1-10 mm diameter) associated with cortical expansion. When several teeth involved radiolucent domelike projection that scallop upward between the roots. 	<p>RADIOGRAPHIC FEATURES:</p> <ul style="list-style-type: none"> Round, oval, well circumscribed, radiolucency with a sclerotic border about 1-3 cm in diameter In Anterior variant, Radiolucency is seen between lower central incisors and first premolars 	
			
<p>HISTOLOGICAL FEATURES:</p> <p>Macroscopic appearance: Blood soaked sponge</p> <p>Microscopic appearance: Spaces filled with unclotted blood surrounded by cellular fibroblastic tissue containing multinucleated giant cells and trabeculae of osteoid and woven bone. These blood filled spaces are not lined by the epithelium</p>	<p>HISTOLOGICAL FEATURES:</p> <ul style="list-style-type: none"> The wall of the defect is lined by a thin band of vascular fibrous connective tissue. Demonstrate a thickened myxofibromatous proliferation, intermixed with trabeculae of cellular & reactive bone. Areas of vascularity, fibrin, erythrocytes and occasional giant cell adjacent to the bone surface. Occasional stringy lace like dystrophic calcification. 	<p>HISTOLOGICAL FEATURES:</p> <ul style="list-style-type: none"> Normal salivary gland tissue is seen Sometimes muscles, fat, connective tissue, lymphoid tissue, blood vessel is seen. 	<p>HISTOLOGICAL FEATURES:</p> <ul style="list-style-type: none"> Mucin-filled cystic cavity surrounded by granulation tissue but the epithelial lining is absent The cystic cavity is often surrounded by a compressed connective tissue wall which contain macrophages, Polymorphonuclear leukocytes, eosinophils, lymphocytes.
			

ODONTOGENIC EPITHELIUM WITHOUT ODONTOGENIC ECTOMESENCYME

- ❖ Ameloblastoma
- ❖ Adenomatoid Odontogenic Tumor (AOT)
- ❖ Calcifying Epithelial Odontogenic Tumor (CEOT)
- ❖ Squamous Odontogenic Tumor (SOT)

ADENOMATOID ODONTOGENIC TUMOR

- It is a benign neoplasm.
- While others have categorized it as a hamartomatous malformation due to the limited size & to the lack of most cases.

CLINICAL FEATURES

➤ SITE:

- 1. unerupted maxillary cuspid
- 2. rarely distal to premolar area
- Asymptomatic swelling
- AOT may occur within the jaw bones /the gingiva.
- Peripheral lesions present as a painless, gingival-colored mass that changes from 1-1.5 cm in diameter.

HISTOLOGICAL FEATURES

MACROSCOPIC FEATURES

It is a soft, roughly spherical mass with a distinct fibrous capsule.

White to tan, solid to crumbly tissue or one/more cystic spaces of varying sizes.

MICROSCOPIC FEATURES

- Multinodular proliferation of spindle, cuboidal & columnar cells in a variety of patterns comprising scattered duct like structures.
- The stellate reticulum like spindle cells & occasionally round or polygonal epithelial cells dominate the tissue between the cell-rich nodules.

AOT- PAS-positive material

AOT-duct like appearance

CALCIFYING EPITHELIAL ODONTOGENIC TUMOR (PINDBERG TUMOR)

- It is a uncommon, benign, odontogenic neoplasm that is exclusively epithelial in origin.

CLINICAL FEATURES

- CEOT occurs most frequently in middle age.
- AGE:- 8-92 years
- SITE- posterior mandibular area involved.
- These lesions are asymptomatic & are aware only of a painless swelling.

CEOT-radiograph

HISTOLOGICAL FEATURES

- Polyhedral epithelial cell with a finely granular eosinophilic cytoplasm & pleomorphic nuclei.
- Intercellular bridges are prominent.
- Presence of a homogenous, eosinophilic substance which has been variously interpreted as amyloid.
- Presence of calcification in the form of Liesegang rings.

Liesegang rings

CEOT: Prominent intercellular bridges and marked nuclear pleomorphism

LEUKEMIA

Definition: Leukaemia is disease characterised by the progressive overproduction of white blood cells which usually appear in the circulating blood in an immature form. A proliferation occur in uncoordinated and independent fashion that leukaemia consider as a true malignant neoplasm.

Classification

Etiology:

- Infectious origin
- Virus e.g. EB virus
- Radiation
- Chemicals e.g. benzene
- Chromosomal abnormalities

Predisposing factor:

- Age
- Genetics
- Monocytes
- Immune competence
- Stress

ORAL MANIFESTATION

- Oral lesion occur in cell type of leukaemia more common in the acute stage of disease.
- According to barket most common monocytic leukaemia.
- Primary clinical manifestation:
 - Gingival hyperplasia
 - Haemorrhage
 - Gingivitis
 - Petechiae
 - Ulceration of mucosa
- In severe disease coats the teeth almost completely hidden by gingiva.
- Gingiva are boggy, edematous and deep red.
- Purpura: lesion of the oral mucosa analogous to the cutaneous ecchymosis may be seen.
- Rapid loosening of the teeth.
- Patient experienced sudden gingival bleeding or gingival hyperplasia should suggest possibility of leukaemia.
- Any disease that causes immunosuppression and disease of blood forming organ may have one or more of the oral finding of acute leukaemia.

ACUTE

- The development of acute leukaemia is sudden, characterised by weakness, fever, headache, general and swelling of lymph node, petechial or ecchymotic haemorrhage in the skin and mucous membrane and evidence of anaemia. Lymphadenopathy is often in the first sign of the disease.
- Cervical lymph nodes are palpable before diagnosis.
- Numerous organs such as the spleen, liver and kidney become enlarged owing to leukaemia infiltration.
- Haemorrhage's are common.

Lab finding:

- Both bleeding time and coagulation time are pro.
- The tourniquet test is usually positive.
- In the early stage leucocyte count may be subnormal, but it rise in the terminal stage to 100000 or more cells per cubic millimetre.
- Bone cell leukaemia is sometimes applied to those types in which the leukaemia cells are highly undifferentiated.

CHRONIC

- This disease may be present for months or even several years before the symptoms lead to discovery.
- It is found by the unexplained leucocytosis is noticed in the haemorrhage examination.
- Anemia often present.

Lab finding:

- Anemia and thrombocytopenia are also common in the chronic leukaemia.
- The leucocytosis may be great white blood cell count of over 50000 cells per cubic millimetre are not uncommon.
- Very low white blood cell count also occur.

SPREAD OF ORAL INFECTION VIA TISSUE SPACES

Clinical Features

- Infection is more common in upper airway as compared to lower airway due to its accessibility, rich vascular supply, and mucociliary clearance.
- Common signs of inflammation.
- Red, hot, swollen, and sore throat.
- Other features depend on causative organism, extent, spread, site, and host's resistance.

Infection can spread via the blood, lymph and the tissue spaces. In dentistry, the tissue spaces of the jaws are the:

1. Periapical abscess space
2. Lateral pharyngeal space
3. Retropharyngeal space
4. Submandibular space
5. Buccal space
6. Sublingual space
7. Sublingual gland space
8. Submental space

Infection spread from maxillary teeth

1. Infection from the maxillary teeth can spread to the maxillary sinus, the maxillary sinus, infraorbital space, submandibular space, buccal space and retropharyngeal space.
2. Infection will spread to the buccal space if the infraorbital space is involved.
3. Infection from the maxillary teeth will spread to the maxillary sinus if the infraorbital space is involved.
4. Infection from the maxillary teeth will spread to the maxillary sinus if the infraorbital space is involved.

Pathways of spread by local tissue channels

Infraorbital space

- Infraorbital space is a potential space lying behind the orbit.
- Boundaries of infraorbital space:

1. Laterally: bounded by zygomatic arch, infraorbital foramen, pyriform foramen, maxillary sinus, maxillary tuberosity, infraorbital foramen, pyriform foramen.
2. Medially: bounded by maxillary sinus, maxillary tuberosity, infraorbital foramen, pyriform foramen.
3. Superiorly: infraorbital foramen.
4. Inferiorly: infraorbital foramen.

Clinical features

- Swelling below the orbit.
- Displacement of upper lip upwards.
- Protrusion of lower lip downwards.

Periapical abscess

- The space between the root of the tooth and the socket proper is called the periapical space.
- Infection in this space can spread to the maxillary sinus, retropharyngeal space, submandibular space, buccal space and retropharyngeal space.

1. Medially: infraorbital space.
2. Laterally: infraorbital space.
3. Superiorly: infraorbital space.
4. Inferiorly: infraorbital space.

Clinical features

- Swelling below the orbit.
- Displacement of upper lip upwards.
- Protrusion of lower lip downwards.

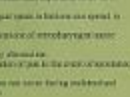

Submental space

- The space between the chin and the neck.
- Boundaries of submental space:

1. Superiorly: chin.
2. Inferiorly: neck.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the chin.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Sublingual space

- The space between the tongue and the floor of the mouth.
- Boundaries of sublingual space:

1. Superiorly: tongue.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Buccal space

- The space between the cheek and the face.
- Boundaries of buccal space:

1. Superiorly: infraorbital space.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

1. Swelling on the side of the face.
2. Displacement of lower lip downwards.
3. Protrusion of upper lip upwards.

Sublingual gland

1. The sublingual gland is located in the sublingual space.
2. The sublingual gland is located in the sublingual space.
3. The sublingual gland is located in the sublingual space.
4. The sublingual gland is located in the sublingual space.
5. The sublingual gland is located in the sublingual space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

1. Swelling below the tongue.
2. Displacement of lower lip downwards.
3. Protrusion of upper lip upwards.

Submandibular space

- The space between the chin and the neck.
- Boundaries of submandibular space:

1. Superiorly: chin.
2. Inferiorly: neck.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the chin.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

1. Swelling below the chin.
2. Displacement of lower lip downwards.
3. Protrusion of upper lip upwards.

Sublingual gland

- The sublingual gland is located in the sublingual space.
- Boundaries of sublingual gland:

1. Superiorly: tongue.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

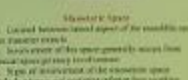

Sublingual gland

- The sublingual gland is located in the sublingual space.
- Boundaries of sublingual gland:

1. Superiorly: tongue.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Infraorbital space

- Swelling below the orbit.
- Displacement of upper lip upwards.
- Protrusion of lower lip downwards.

Periapical abscess

- The space between the root of the tooth and the socket proper is called the periapical space.
- Infection in this space can spread to the maxillary sinus, retropharyngeal space, submandibular space, buccal space and retropharyngeal space.

Clinical features

- Swelling below the orbit.
- Displacement of upper lip upwards.
- Protrusion of lower lip downwards.

Submental space

- The space between the chin and the neck.
- Boundaries of submental space:

1. Superiorly: chin.
2. Inferiorly: neck.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the chin.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Sublingual space

- The space between the tongue and the floor of the mouth.
- Boundaries of sublingual space:

1. Superiorly: tongue.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Periapical abscess

- The space between the root of the tooth and the socket proper is called the periapical space.
- Infection in this space can spread to the maxillary sinus, retropharyngeal space, submandibular space, buccal space and retropharyngeal space.

1. Medially: infraorbital space.
2. Laterally: infraorbital space.
3. Superiorly: infraorbital space.
4. Inferiorly: infraorbital space.

Clinical features

- Swelling below the orbit.
- Displacement of upper lip upwards.
- Protrusion of lower lip downwards.

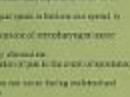

Submental space

- The space between the chin and the neck.
- Boundaries of submental space:

1. Superiorly: chin.
2. Inferiorly: neck.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the chin.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Sublingual space

- The space between the tongue and the floor of the mouth.
- Boundaries of sublingual space:

1. Superiorly: tongue.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling below the tongue.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Buccal space

- The space between the cheek and the face.
- Boundaries of buccal space:

1. Superiorly: infraorbital space.
2. Inferiorly: floor of the mouth.
3. Medially: infraorbital space.
4. Laterally: infraorbital space.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

Clinical features

- Swelling on the side of the face.
- Displacement of lower lip downwards.
- Protrusion of upper lip upwards.

FINE NEEDLE ASPIRATION CYTOLOGY

- Traditional cytology is usually accompanied with Fine Needle Aspiration Cytology (FNAC).
- About 20 years before an advance in the fine needle and the emergence of the technique has enormously increased the scope of diagnostic cytology.

Applications of FNAC

- It is a non-invasive FNAC is commonly used for diagnosis of palpable cystic lesions.
- Palpable lesions commonly diagnosed are: breast lumps, enlarged lymph nodes, enlarged thyroid and parotid and other masses.
- The majority of cases of palpable adenoma of breast and the testicles are also frequently aspirated for FNAC.
- Other sites commonly aspirable for FNAC are: the prostate, pelvic lymph nodes, liver and joint spaces, lung, pleural effusion, etc.

Advantages of FNAC.

- FNAC is an office / OPD procedure and no hospitalization is required.
- No anaesthesia is required.
- The procedure is quick and painless.
- Multiple aspirations are possible without anaesthesia, whereas requiring a surgical biopsy is necessary and uncomfortable for the patient.
- Results are obtained rapidly as the reports being available in a matter of hours while histopathological reports are available after a longer duration.
- It is a low cost procedure which is cost-effective.

General Procedure for FNAC

Materials for FNAC

Needles

- 22 gauge disposable needle of 30mm length-cystic lesions
- 25 gauge FNAC of palpable masses
- 18 or 24 gauge aspirable needle of 20mm length-lymph nodes and children.
- 22 gauge 100mm in length sampling the lung and abdominal masses.
- 22 to 20 gauge 20mm spinal position needle-spinal fluid.
- Needles of up to 200mm length-osteoblast osteogel FNAC of the prostate and ovary.
- 18 gauge-aspirator of large lesions.

Syringes

- Syringes of 10 to 20ml capacity are available.
- Syringe holder is given a wide base. The syringe aspirator is placed in aspirable syringe.
- Needle with a wide lumen should be used to ensure a proper flow of aspirate inside both aspirable syringe.

Glass Slides and Fixative

- There are two main types of glass slides used for FNAC. A wide surface area (75 or 75mm x 25mm) and a narrow one (75mm x 25mm x 12.5mm) are used for FNAC.

Method of Aspiration FNAC

- The patient is asked to lie prone in a position that best exposes the target area.
- The target area is thoroughly palpated and the approximate position of the lesion is noted.
- The skin over the lesion is sterilized with an antiseptic pad.
- The needle is inserted by the palpating hand of the operator or by assistant.
- The needle is introduced into a target area. On reaching the lesion the plunger of the syringe is retracted and a least 10ml of aspirate is applied while moving the needle back and forth within the lesion.
- Aspiration is continued when aspirated material is blood because visible at the lower hub of the needle.
- On completion of aspiration, suction is released and pressure saline syringe attached to replace buffer will withdraw the needle.
- Following withdrawal of the needle from the lesion, pressure is applied to the site of puncture by the assistant for 2 to 3 minutes in order to arrest bleeding if any.

Preparation of Smears for FNAC

- Aspirated specimen on the slide can be prepared with spreader.
- The spreader (perforated aspirator) are made of metal and prepared with a glass slide on a thick cover slip.
- Thick and gooey specimen is required to avoid the spreading with. Droplets of fluid or viscous material are retained under the edge of the spreader using a 180° cover slip and pulled over a blood smear.
- Particulate material which is seen along the edges and at the end of smears, is then crush covered by covering a spreading slide.

Preparation of Smears for FNAC

- Prepara: smears are either made from an smear, but the material of smears are immediately covered in 95% alcohol.
- The preparation of the smears is done in the laboratory and sent to the laboratory for histology and smears staining. The remaining smears are stored in a large paper bag.
- Microscopic smears are stored in a separate bag.
- Microscopic smears are kept in a separate bag.
- Microscopic smears are kept in a separate bag.
- Microscopic smears are kept in a separate bag.

Microscopic appearance

Complications and Hazards

- Haematomas
- Infection
- Pneumothorax
- Dissemination of tumour

Limitation of FNAC

- The main limitation of FNAC lies in the fact that only a small proportion of cells is sent back by the procedure.
- The reliability of the test, thus, depends on the adequacy of the sample and its representation of the lesion.
- An inadequate sample which is not representative of the true lesion results in false negative diagnosis. A true negative result requires of metastases, the process should be investigated further.
- FNAC may be reported as a negative biopsy performed in which a tissue of origin is not specified.
- Lack of response observed, infection or other related complications results further loss of FNAC.

HISTOPATHOLOGY OF MALIGNANT TUMORS OF EPITHELIAL ORIGIN

- ❖ Basal cell Carcinoma
- ❖ Adenoid Squamous cell Carcinoma
- ❖ Squamous cell Carcinoma
- ❖ Spindle cell Carcinoma
- ❖ Verrucous Carcinoma
- ❖ Adenosquamous Carcinoma
- ❖ Basaloid Squamous cell Carcinoma
- ❖ Undifferentiated Carcinoma

BASAL CELL CARCINOMA
Well demarcated islands showing peripheral palisading
(L) Low power (R) high power view

BASAL CELL CARCINOMA

1. Keratin pearls formation of keratin cysts may be seen from nests of cells (L&R) slides
2. Peripheral palisading arrangement
3. Absence of mitotic figures
4. Presence of characteristic clefts, keratin & granular pattern

VERRUCOUS CARCINOMA

1. Thick surface of squamous epithelium (warty)
2. Hyperkeratosis
3. Malignant cells at the basal part
4. Peripheral palisading
5. Keratin pearls
6. Little or no mitotic activity

SQUAMOUS CELL CARCINOMA (WELL DIFFERENTIATED)

Arrow shows keratin pearls

1. Thick keratin with keratin cysts (keratin)
2. Cellular pleomorphism, nuclear hyperchromatism, a band of basal cells, and mitotic activity
3. Infiltrative growth

MALIGNANT MELANOMA

1. Malignant melanocytes with extensive cellular pleomorphism and nuclear hyperchromatism present
2. Numerous mitotic activity with production of large amounts of melanin pigment
3. Specific histologic pattern according to arrangement of tumor cells (Hutchinson's freckles, superficial spreading, nodular)

SQUAMOUS CELL CARCINOMA (POORLY DIFFERENTIATED)

1. Infiltrative growth
2. Poorly differentiated
3. High mitotic activity
4. Absence of keratin pearls

SPINDLE CELL CARCINOMA

1. Proliferation of spindle or spindled cells resembling fibroblasts
2. Basophilic cytoplasmic appearance of epithelial cells
3. Minimum degree of epithelial dysplasia with little or no keratin formation
4. Inflammatory cell infiltration in connective tissue stroma

Dentinogenesis

Dentinogenesis is the process of formation of dentin.

It is two phase sequence: a) Odontoblast differentiation b) Formation of organic matrix

Odontoblast differentiation

- > Odontoblast differentiate from the cells of dental papilla.
- > They change from an ovoid to columnar shape nuclei become basally oriented.
- > One or several processes arise from apical end.
- > Prolin appears in RER and golgi apparatus
- > Key protein secreted by odontoblast is dentin phosphoprotein.

Formation of Organic Matrix

- > Prolin appears and migrates into cell process in dense granules and emptied into extracellular collagenous matrix in predentin.
- > The odontoblast secrete both collagen and intercollagen substance proteoglycans.
- > As the cell recedes it leaves behind a single extension and several initial process join into one which becomes enclosed in a tubule
- > Odontoblasts increases to approximately 40 micrometer.

Mineralization

Control of mineralization

- > Mineralization is achieved by continuous deposition of mineral.
- > It is initiated by producing matrix vesicles and proteins that can regulate mineral deposition and by adapting organic matrix at mineralization end, so that it receives the mineral deposits.
- > Presence of alkaline phosphatase activity and calcium adenosinetriphosphatase activity at the distal end of the cell also is consistent with a cellular implication in the transport and release of mineral ions into forming dentin layers.

Pattern of mineralization

- > Histologically two patterns: a) Globular b) Linear Calcification
- > Depends on rate of dentin formation
- > Globular calcification involves deposition of crystal in several discrete areas of matrix by heterogenous capture in collagen, mainly seen in mantle dentin. With continued crystal growth, globular masses are formed that continue to enlarge and eventually use to form a single calcified mass.
- > When it is necessary to form dentin fastest, the dentin will form in globular pattern.
- > When the dentin form slowly, the linear pattern will be use.

Formation of Root Dentin

- > The epithelial cells of Hertwig's Root Sheath initiate the differentiation of odontoblasts that form root dentin
- > Root dentin increasingly is recognized as being structurally and compositionally different from coronal dentin
- > Phosphoryn content of root dentin is less than coronal dentin

Secondary Dentinogenesis

- > It is laid down after root formation is completed
- > Its formation is achieved at much slower pace
- > It can be distinguished histologically from primary dentin by a demarcation line, a slight differential in staining a less regular organization of dentinal tubules.

Tertiary Dentinogenesis

- > Tertiary dentin or reparative dentin is deposited at specific sites in response to injury by damaged odontoblasts or replacement cells that are recruited from pulp
- > The rate of deposition depends on degree of injury, more severe the injury more rapid the rate of dentin deposition.

AMELOGENESIS

On the basis of ultrastructure and composition, two processes are involved in the development of enamel.

1. Organic Matrix Formation.

2. Mineralization.

Although the inception of mineralization does not await the completion of matrix formation, the two processes will be treated separately.

A. Organic Matrix Formation

- The ameloblasts start their secretory activity after a thin layer of dentin is formed. The islands of enamel matrix are deposited along the predentin.
- As enamel deposition proceeds, a thin continuous layer of enamel is formed along the dentin.
- Amelogenins are major component of enamel matrix proteins. It undergoes extra cellular degradation by proteolytic enzyme like matrix metalloproteinase. Most of the secreted amelogenins are removed during maturation.
- Amelogenin forms fibrotopic gel which can be easily squeezed out by pressure of growing crystals.
- Ameloblastin and enamelin are other important proteins of enamel matrix.

Development Of Tome's Process

- The projections of ameloblasts into enamel matrix have been called **Tome's Process**.
- This Tome's process also contains secretory granules, endoplasmic reticulum and mitochondria.
- The junctional complexes which encircle the ameloblasts at their distal and proximal ends have fine radiating actin filaments.
- The junctional complexes which form at the distal end are called **Distal Terminal Bars**. These terminal bars separate the Tome's Process from the cell proper.
- Secretions from areas close to junctional complexes and adjacent ameloblast form inter rod enamel.
- They occur earlier and serve to outline the pit into which secretions from Tome's Process occurs later to form the enamel rod.

Transition

- The changes occurring after secretory stage and prior to onset of maturation process is called **Transition Stage**.
- In this stage,
 - Ameloblast reduce in height,
 - Enamel secretion stops completely,
 - Process of amelogenin removal starts,
 - About 50% ameloblast undergo apoptosis.

Modulation

- Ameloblast alternate cyclically in developing smooth ended and rough ended borders in apical cytoplasm during maturative stage which is called **Modulation**.
- Smooth Ended:** Leaky distal and tight proximal junction.
 - It leaks small proteins and water into forming enamel.
- Ruffle Ended:** Proximal leaky and tight distal junction.
 - It promotes calcium entry into the forming enamel.

B. Mineralization

- In the first stage, an immediate partial mineralization of about 25-30% of the total mineral content occurs in the matrix as it is laid down.
- The second stage of maturation occurs very rapidly after the first stage. It is characterized by the gradual completion of mineralization till the inorganic content reaches 96%.
- Maturation involves the resorption of enamel matrix by the ameloblasts through,
 - Removal of large amounts of water.
 - Removal of certain part of enamel proteins.
 - Growth of the pre-existing crystals.

TOOTH DEVELOPMENT

DEVELOPMENTAL STAGES

Tooth development is a continuous process. The histology of development of tooth divides into 4 stages as:-

1. Bud stage
2. Cap stage
3. Bell stage
4. Advance bell stage

BUD STAGE

- The epithelium of the dental laminae is separated from the underlying ectomesenchyme by basement membrane.
- Differentiation of each dental laminae, round or oval swellings arise from the basement membrane corresponding to the future positions of deciduous teeth.

- In bud stage, there are ectopically located low columnar cells and centrally located polygonal cells.
- The ectomesenchymal cap (ectomesenchymal cap condensation) surrounding tooth bud condenses.
- The area of ectomesenchymal condensation immediately subjacent to the enamel organ is **DENTAL PAPILLA**.
- The condensed ectomesenchyme that surrounds tooth bud and dental papilla is the **DENTAL SAC**.

CAP STAGE

Shallow invagination on deep surface of the bud gives rise to:

OUTER AND INNER ENAMEL EPITHELIUM

- Peripheral cells are cuboidal, covers convexity, called the **outer enamel epithelium**.
- Cells in concavity becomes tall, columnar cells, called **inner enamel epithelium**.

STELLATE RETICULUM:

- Polygonal cells located in the centre of epithelial enamel organ becomes star-shaped called **stellate reticulum**. Glycoaminoglycans in ground substance and remains in contact with each other by cytoplasmic processes.
- The cells in the centre of the enamel organ are densely packed and form the **ENAMEL KNOT**.

- The vertical extension of enamel knot is called **ENAMEL CORD**.

- When enamel cord extends to meet the outer enamel epithelium it is called **ENAMEL SEPTUM**.
- The outer enamel epithelium at the point of meeting shows a small depression and this is called **ENAMEL NAVEL**.

DENTAL PAPILLA:-

- "The ectomesenchyme (neural crest cells) that is partially enclosed by the invaginated portion of the inner enamel epithelium proliferates. It condenses to form the dental papilla which is formative organ of dentin and primordium of pulp."

DENTAL SAC:-

- Marginal condensation in the ectomesenchyme surrounding the enamel organ and dental papilla, a denser and more fibrous layer develops, which is the **PRIMITIVE DENTAL SAC**.

BELL STAGE

- As the invagination of the epithelium deepens and its margins continue to grow, the enamel organ assumes a bell shape.
- Four different types of epithelial cells can be distinguished of the bell stage of the enamel organ are:-

1. INNER ENAMEL EPITHELIUM:

- It consists of a single layer of cells that differentiate prior to amelogenesis into tall columnar cells called **AMELOBLASTS**.
- These cells are 4 to 5 µm in diameter and about 40 µm high.

2. STRATUM INTERMEDIUM:

- A few layers of squamous cells form the **stratum intermedium**, between the inner enamel epithelium and the stellate reticulum.
- These cells are closely attached by desmosomes and gap junctions.

3. STELLATE RETICULUM:

- The stellate reticulum expands further, mainly by an increase in the amount of intercellular fluid.
- The cells are star-shaped, with long processes that anastomose with those of adjacent cells.

4. OUTER ENAMEL EPITHELIUM:

- The cells of this flatten to form a low cuboidal.
- At the end of the bell stage, preparatory to and during the formation of enamel, formerly smooth surface of the outer enamel epithelium is laid in folds.

DENTAL LAMINA:

- It is seen to extend lingually and is termed **successional dental lamina** as it gives to enamel organs of permanent deciduous teeth.

DENTAL PAPILLA:

- It is enclosed in the invaginated portion of the enamel organ. Before the inner enamel epithelium begins to produce enamel, the peripheral cells of the mesenchymal dental papilla differentiate into **ODONTOBLASTS**.

- Before formation of dental tissues, the dental sac shows a circular arrangement of its fibers and resembles a capsular structure.

ADVANCED BELL STAGE:

- During this the boundary between inner enamel epithelium and odontoblasts outlines the future **dentinoenamel junction**.
- In addition the cervical portion of the enamel organ gives rise to the epithelial root sheath of Hertwig.

- The Hertwig's epithelial root sheath (HERS) outlines the future root and is thus responsible for the shape, length, size and number of roots.

ROOT FORMATION

- Hertwig's root sheath consists of outer and inner enamel epithelia only.
- Clumps of epithelial remnants near external surface of root which are found in periodontal ligament of erupted teeth are called **REST OF MALASSEZ**.
- Root sheath forms epithelial diaphragm which is fixed during development and growth of root.
- If the cells of epithelial root sheath remain adherent to the dentin surface, they may differentiate into fully functioning ameloblasts and produce enamel. Such droplets of enamel are called **ENAMEL PEARLS**.

ENAMEL

ENAMEL RODS

- These are the fundamental organizational unit of enamel
- Number 5 million to 12 million
- The rods are rarely straight, they follow a wavy road to form dentin to enamel surface
- Under light microscope, they appear longitudinal, or sometimes transverse resembling fish scales

ULTRASTRUCTURALLY

- Enamel give a keyhole or paddle shaped prism appearance
- When cut longitudinally, sections pass through the "heads" or "tails" of one row of rods and "bar" of an adjacent row
- Interrod substance**
- The rods are cemented together by enamel substance, whose crystals are oriented in a direction different from those making up the rod
- Rod sheath**
- The boundary between rod and interrod enamel is defined by a narrow space containing organic material known as rod sheath

INCREMENTAL LINE

- They represent the fundamental unit of deposition of layers of rods to structure in basic enamel structure or growth cycle called as a cycle
- Usually span 8 enamel lamellae, 8-12 microns area of formation
- Micronoscopically they appear as transverse bands surrounding the top of dentin

CROSS STRIATIONS

- Striations appear because of enamel rod built up sequentially and start by dark lines, which represent enamel lamellae formed by its formation
- The cross striations demonstrate rod apposition and demarcate their width by the action of rod sheath
- They appear as a narrow strip of about 0.5 microns
- The striations are more pronounced in enamel that is translucently crystalline

NEONATAL LINE

- The neonatal line is a profile for band of incremental growth line seen in the histologic section of a deciduous tooth
- It represents demarcation between prenatal & postnatal enamel and explains due to abrupt change in the environment & nutrition of the infant
- Perinatal enamel is better developed than neonatal enamel, hence it appears whiter in color than the latter

DIRECTION OF RODS

At occlusal/cusp	Vertical
At middle	Oblique
At cervical	Horizontal

SURFACE STRUCTURES

PRISMLESS ENAMEL

- Enamelless layer more heavily mineralized the enamel area of enamel surface
- Main dentin
- All spaces empty (available for penetration of water or bacteria)

PERICRYMATA

- Thinness seen the greater portion of enamel surface, between the two enamel lamellae (of area of rod)
- Can penetrate with silver in ICI
- 200x in figure of ICI
- 300x near occlusal & cervical edge

ENAMEL CAPS

- Obvious shallow pits of about 1-3 microns diameter in enamel and enamel surface, due to which small amounts of about 20-30% are formed - enamel caps

ENAMEL BROCHS

- Large enamel structure
- Also called Karyakid's phenomenon
- Defective membrane covering the width of newly erupted teeth, but later removed by maturation
- Formed a closed lateral layers found beneath epithelium, eventually occluded by subsequent or replacement enamel formation

HYPOCALCIFIED STRUCTURE

ENAMEL LAMELLAE

- Enamel lamellae are thin leaf like structures that extend from the enamel surface toward the dentinoenamel junction
- Type A - lamellae composed of poorly calcified rod segments. It is restricted to the enamel
- Type B - Lamellae composed of degenerated cells. It reach to dentin
- Type C - lamellae arising of erupted teeth where the cracks are filled with organic matter

ENAMEL TUFTS

- Enamel tuft is a narrow ribbon like structure the inner end of which arises from dentin
- They are named so as they give appearance like tufts of grass
- They root into enamel up to thinning 1/3th of its thickness
- They are hypocalcified structure & give black appearance in ground section

ENAMEL SPINDLES

- Some odontoblast's processes enter enamel and because thick they are to be called as enamel spindles
- It is a hypocalcified structure
- They are small needle like structures in which air is filled
- They give black appearance in ground section

ENAMELED ENAMEL

- If the tissue are not utilized fully, they left near the dentin in the region of cuspal edges, bundles of rod seem to interdigitate more irregularly
- The enamel appears of coarse surface - "enamel craters"

BIUNTERDIG-ROD CONTACT

- Enamel due to change in the direction of rods to a result of functional adaptation
- Appear as alternating dark & light band arising from rods
- Angle between dark & light bands is about 40 degrees
- Dark band is called as over & light band is called as under

DENTINOENAMEL JUNCTION

- The junction separating enamel and dentin
- It is a well organized structure where the continuity is seen towards dentin and normally towards enamel
- It is 100x thick

Cells and fibers of Periodontal Ligament

PDL is a connective tissue structure that attaches the tooth to the alveolar bone. Components of PDL includes cells, fibers, ground substance, etc.

CELLS

A. Synthetic Cells

They synthesize proteins that form extracellular substance of connective tissue.

- Osteoblasts**
 - Cuboidal cells with prominent round nucleus at the basal end lining the tooth socket.
 - Function: Formation of bony matrix of bone and mineralization of matrix.
- Concreteblasts**
 - Distributed along retentive surface of PDL ligaments.
 - Cuboidal with large vesicular nucleus and prominent nucleolus.
 - Function: Formation of cementum.
- Fibroblasts**
 - They are predominant cells in PDL.
 - They are fusiform in shape and lie parallel to tooth surface.
 - Function: Formation of proteins like GAG, glycoproteins, collagens, elastin, etc.

B. Resorptive Cells

- Osteoclasts**
 - Large and multinucleated cells found in Howship's lacunae or resorptive end of bone spines.
 - Function: Resorption of bone that allows functional changes in position of teeth.
- Cementoclasts**
 - Resembles osteoclasts and occasionally found in normal functioning periodontal ligaments.
 - They are macrophage-like or multi-nucleated giant cells.
 - Function: Resorb cementum.
- Fibroblasts**
 - Spindle form cells with large nucleus.
 - Function: Rapid degradation of collagen by fibroblast plasminogen.

C. Progenitor Cells

- Have capacity to undergo mitotic cell division.
- All about concentration in location adjacent to blood vessels and also enter PDL through cell canal embedded spaces.
- They are derived from undifferentiated mesenchymal cells.

D. Epithelial Cell Rests Of Malassez

- They are remnants of IERS found closer to cementum.
- Appears cluster like with prominent nucleus and scanty cytoplasm.
- Undergo rapid proliferation and give rise to certain pathogenic conditions like cysts and tumors of jaw.

E. Defense Cells

- Mast Cells**
 - They are small rounded cells with centrally located nucleus.
 - They are found adjacent to blood vessels.
 - Function: Important role in regulation of endothelial and fibroblast cell population.
 - Mast cell histamine plays role in inflammatory reaction.
- Macrophages (Leucocytes cells)**
 - Round or oval cells with kidney shaped nucleus.
 - Derived from blood monocyte, found adjacent to blood vessels.
 - Function: Phagocytosing dead cell and secreting growth factors.
- Lymphocytes**
 - Ovoid nuclei seen in PDL.
 - They possess granules that resemble of one or more crystalline structure.
 - Function: Phagocytosis.

FIBERS

Collagenous Fibers:

- They are fibers containing collagen which is a protein composed of different amino acids. These are principal fibers.
- Collagen is gathered to form bundles approx. 2 microns in diameter while each collagen bundle, subunits are present called Collagen fibrils.
- They are classified into:
 - Alveolar crest group**
 - Extends obliquely from cementum beneath junctional epithelium to alveolar crest.
 - Functional fibers** (rod, lifting, intrusive, extrusive and rotational fibers)
 - Run at right angles to long axis of tooth from cementum to alveolar bone and parallel to occlusal plane of arch.
 - Function: Resist horizontal and tipping forces.
 - Oblique group**
 - Most numerous and occupy two-third of ligament.
 - Inserted into alveolar bone at position coronal to their attachment to cementum.
 - Function: Resist vertical and intrusive force.
 - Apical group**
 - Absent in incompletely formed root.
 - Focus cementum to root tip and fibers gets anchored into fringes of bony socket.
 - Function: Resist force of luxation, prevent tooth tipping.
 - Intraradicular group**
 - They are inserted into cementum from crest of interradicular septum in a undivided tooth.
 - Function: Resist tooth tipping, tipping and luxation.

Elastic Fibers:

- Three types, which are histologically and ultra structurally different.
- Mature elastic fibers**
 - Elastic protein contains a high percentage of glycine, proline and hydroxylic residues.
 - These fibers are observed only in the wall of different blood vessels.
- Young elastic fibers**
 - Fibers are seen as bundles of silver fibrils embedded in a small amount of amorphous elastin.
 - Observed only within the fibers of gingival ligament.
- Dustlike fibers**
 - They are type of immature elastic fibers.
 - Appears in consist of thickened basal component only.

Sharpey's fibers:

- Collagen fibers are embedded in cementum on one side of PDL, span and into alveolar bone on another.
- Sharpey's fibers is another cementum are mineralized body.
- For Sharpey's fibers pass through bone to alveolar process as transverse fibers.

THE MANDIBULAR CANINE

Introduction

The mandibular canine crown is narrower mesiodistally than that of the maxillary canine. The root may be as long as the maxillary canine, but usually it is somewhat shorter.

The labiolingual dimension of crown and root is usually a fraction of a millimeter less, adapting this measurement to the other anterior teeth.

The lingual surface of the crown is smoother, with less cingulum development and less bulk to the marginal ridge.

The cusp of the mandibular canine is not as well-developed as that of the maxillary canine, and the cusp ridge are thinner labiolingually.

A variation in the form of the mandibular canine is bifurcated root. This variation is not rare.

- Here,
- MCR - Mesial cusp ridge
 - MMR - Mesial marginal ridge
 - MLF - Mesiolingual fossa
 - DMR - Distal marginal ridge
 - DCR - Distal cusp ridge
 - C - Cingulum
 - CL - Cervical line
 - LR - Lingual ridge
 - DLF - Distolingual fossa

Chronology & Measurement Table

Presence of DLF's soon	4 To 5 Year
Root completed	6 To 7 year
Eruption	8 To 10 Year
Root Completed	12 To 14 year

DEVELOPMENTAL AGE (MONTHS)	MAX. CROWN HEIGHT (MM)	MAX. CROWN WIDTH (MM)	MAX. CROWN LENGTH (MM)	MAX. CROWN BREADTH (MM)	MAX. CROWN DEPTH (MM)	MAX. CROWN AREA (MM ²)	MAX. CROWN PERIMETER (MM)	MAX. CROWN VOLUME (MM ³)
11.5*	16.8	7.8	1.5	1.5	1.0	2.3	1.8	

Labial Aspect

The mesiodistal dimensions of the mandibular canine are 1mm less than maxillary canine.

The crown of the mandibular canine appear longer. The crown is narrower mesiodistally and the height of the contact areas above the cervix.

The mesial outline of the crown is nearly straight with the center of the root with the mesial contact area being near the mesioincisal angle.

The distal contact area is more toward the incisal aspect than that of the maxillary canine but it not up to the level of the mesial aspect.

The cervical line labially has a semicircular curvature apically.

Many mandibular canine give the impression from this aspect of being bent distally on the root base.

Labial ridge is less prominent than maxillary canine.

Lingual Aspect

The lingual surface of the crown is flatter, simulating the lingual surface of mandibular incisor.

The cingulum is smooth and poorly developed.

The marginal ridge are less distinct. The lingual surface of the crown is smooth and regular.

The lingual portion of the root is narrower relatively than that of the maxillary canine.

Mesial Aspect

The mandibular canine has less curvature labially on the crown with very little curvature directly above the cervical line.

The curvature at the cervical portion is less than 0.5mm. The lingual outline of the crown is curved that of the maxillary canine, but it differs in degree.

The cingulum is not as pronounced and the incisal portion of the crown is thinner labiolingually, which allows the cusp to appear more pointed and the cusp ridge to appear more slender.

The tip of the cusp is more nearly centered over the root, with a lingual placement in some cases comparable to the placement of incisal ridge on mandibular incisors.

The developmental depression mesially on the root of the mandibular canine is more pronounced and some time quite deep.

Distal Aspect

Incisal portion is blunt in maxillary canine. Incisal portion is sharp in mandibular canine.

Labial surface is less convex in maxillary canine. In mandibular canine labial surface is more convex.

Little difference from the distal aspect can be seen between mandibular and maxillary canine in this FIGURE*

Incisal Aspect

The outline of the crowns of mandibular and maxillary canine from the incisal aspect are often similar.

The cusp tip and mesial cusp ridge are more likely to be inclined in a lingual direction in the mandibular canine with the distal ridge and the contact area extension distinctly so.

The mesiodistal dimension is less than the labiolingual dimension.

The outline of the mesial surfaces are less curved.

The Root

Second longest root of all teeth.

Less wider mesiodistally.

Root apex is sharp.

Distal deflection of apex is less greater.

The lingual portion of the root is narrower relatively than that of the maxillary canine.

The developmental depression mesially on the root of the mandibular canine is more pronounced and some time quite deep.

• The Permanent Maxillary Second Premolar •

INTRODUCTION

It develops from four lobes.
This tooth supplements the first premolar in its functions.
It is a more rounded tooth with a single root.

CHRONOLOGY

First evidence of calcification	: 2-2.25 years
Crown completed	: 6-7 years
Eruption	: 10-12 years
Root completed	: 12-14 years

MEASUREMENT TABLE

	Maxillary 2 nd Premolar (mm)
Cervico- incisal length of crown	8.5
Length of root	14.0
Mesiodistal diameter of crown	7.0
Mesiodistal diameter of crown at cervix	5.0
Labio or bucco-lingual diameter of crown	9.0
Labio or bucco-lingual diameter at cervix	8.0
Curvature of cervical line-mesial	1.0
Curvature of cervical line-distal	0.0

BUCCAL ASPECT

Buccal surface is smaller and less convex.
Buccal ridge is less prominent.
Tip of buccal cusp is less sharp.
Distal slope of buccal cusp ridge is longer than mesial slope.
The crown and root are thicker at their cervical portions.

LINGUAL ASPECT

Lingual surface is larger and more convex.
Lingual cusp appears longer making crown longer on lingual side.

MESIAL ASPECT

The cusps of the second premolar are shorter, with the buccal and lingual cusps more nearly the same length.
Greater distance between cusps widens the occlusal surface buccolingually.
No developmental depression is evident on the mesial surface of the crown.
The crown surface is convex.
A shallow developmental groove appears on the single tapered root.
No deep developmental groove crossing the mesial marginal ridge.

DISTAL ASPECT

The distal root depression is deeper than the mesial depression on the maxillary second premolar.

OCCLUSAL ASPECT

The outline of the crown is more rounded or oval, rather than angular.
The central developmental groove is shorter and more irregular.
This supplementary groove terminates in a shallow depression of the enamel.
This arrangement makes for an irregular occlusal surface and gives the surface a very wrinkled appearance.

Professor & Head : Dr. Binita Trivedi; Reader : Dr. Suchi Shah; Senior Lecturer : Dr. Brijesh Patel; Lecturers : Dr. Amit Patel and Dr. Maitrik Shah

PERMANENT MAXILLARY CANINE

INTRODUCTION :-

- Canine is the third tooth from median line, right and left, in the maxilla.
- It is commonly referred as "cornerstone" of the dental arches.
- Their resemblance to the prehensile tooth of the carnivore gave the term CANINE.
- They are very efficient in function, stability and maintaining natural facial expressions.

CHRONOLOGY:-

- First evidence of calcification: 4-5 months
- Enamel completed: 6-7 years
- Eruption: 11-12 years
- Root completed: 13-15 years

DIMENSIONS:-

- Cervicoincisal length of the crown: 10.0mm
- Length of root: 17 mm
- Mesiodistal diameter of the crown: 7.5 mm
- Mesiodistal diameter of the crown at cervix: 5.5 mm
- Labiolingual diameter of the crown: 8 mm
- Labiolingual diameter of the crown at cervix: 7mm

Detailed Description

LABIAL ASPECT:-

- The Cusp has mesial and distal slopes with mesial being shorter.
- Shallow depressions give rise to three labial lobes.
- Middle one has greater development, thus produces a ridge, whose all areas exhibit convexity except for insignificant developmental lines in enamel.
- The labial surface of crown is smooth without developmental lines.
- Mostly the cusp tip is on a line with the centre of the root.

LINGUAL ASPECT:-

- The cingulum is large and in some instances pointed like a small cusp.
- At times lingual surface of the canine crown is so smooth that fossae or minor ridges are difficult to distinguish.
- Usually the smooth cingulum marginal ridges and lingual portion of the incisal ridges are confluent with the little evidence of developmental grooves.

MESIAL ASPECT:-

- The outline of the crown is wedge shaped and the greatest measurement is at the cervical third.
- Many canines show a flattened area labially at the cervical third of the crown.
- The entire labial outline is more convex than the maxillary central incisor.
- The mesial surface of the canine crown presents convexities at all points except for a small, circumscribed area above the contact area, where the surface is concave and flat between that area and the cervical line.

DISTAL ASPECT:-

- The distal aspect is similar to the mesial one but with some variations, which are as follows.
- The cervical line exhibits less curvature towards the cusp ridge; the distal marginal ridge is heavier and more irregular in outline; the surface displays more concavity above the contact area.

INCISAL ASPECT:-

- The labiolingual dimension is greater than the mesiodistal.
- The tip of the cusp is labial to the centre of the crown labiolingually, and mesial to the centre mesiodistally.
- The crown of this tooth gives the impression of having the entire distal portion stretched to make a contact with the first premolar.
- Buccal ridge is noticeable labially from the incisal aspect.

The Root:-

- Labially root is conical with a bluntly pointed apex and has a sharp curve at apical third.
- Root is narrower lingually than labially.
- The lingual ridge of the root is rather narrow but is smooth and convex at all points from the cervical line to the apical end.
- Mesially, the outline of the root is conical and the root may curve labially towards the apical third.
- The developmental depression on the distal side of the root is more pronounced.

--	--

PERMANENT MANDIBULAR SECOND PREMOLAR

PULP CHAMBERS & CANALS

*Bucco-lingual section:

There is larger & wider pulp cavity than of the mandibular 1st premolar. The pulp chambers are usually large & may gently taper into pulp canal.

*Mesio-distal section:

Usually has one root & canal that may be curved, but usually in the distal section.

CUSP TYPES

*Two Cusp type:

This form of premolar is more rounded having a buccal cusp & lingual cusp.

*Three cusp type:

This form of premolar is more angular & has one buccal cusp & two lingual cusps.

INTRODUCTION

- The Second mandibular premolar is the larger of the two mandibular premolars.
- This tooth assumes two common forms-
 - three cusp type
 - two cusp type

CRONOLOGY

- First evidence of calcification - 21/2 to 21/2yr
- Enamel completed - 6 to 7yr
- Eruption - 11 to 12yr
- Root completed - 13 to 14yr

MEASUREMENT TABLE

	Cerico-Occisal Length of root	Mesio-distal Diameter of crown	Mesio-distal diameter of crown at cervix	Labio or bucco diameter of crown at cervix	Labio or bucco-lingual diameter of crown at cervix	Curve-ture of cervix -Mesial-Distal	Curve-ture of cervix
Dimensions	8.6	14.5	7.6	5.8	8.0	7.8	1.6

BUCCAL ASPECT

- It resembles the mandibular first premolar from the buccal aspect.
- The buccal cusp is shorter than the first premolar.
- The mesiobuccal & distobuccal cusp ridges presenting angulation of less degree.
- The contact area are broad because of the short buccal cusp.

LINGUAL ASPECT

- The lingual surface is smooth & spherical.
- The root is wide lingually.
- The two cusp type has no groove, but it shows a developmental depression distolingually.
- The lingual portion of root is smoothly convex for most of its length.

MESIAL ASPECT

- The crown & root are wider buccolingually.
- The buccal cusp is not so nearly centered over the root trunk & it is shorter.
- The mesial marginal ridge is at right angles to the long axis of the tooth.

DISTAL ASPECT

- It is similar to the mesial aspect.
- Distal marginal ridge is at a lower level than the mesial marginal ridge.

OCCUSAL ASPECT

- The outline of the crown is rounded lingual to the buccal cusp ridge.
- The mesiolingual & distolingual line angles are rounded.
- The three-cusp type appears square lingual & two-cusp type appears round lingual to the buccal cusp ridge.
- Buccal cusp is largest.
- Deep developmental groove converge in central pit & forms "Y" shape on occlusal surface.

Difference Between Permanent Mandibular First and Second Premolar

Mandibular Right First Premolar

- BC: Buccal Cusp
- LC: Lingual Cusp
- BTR: Buccal Triangular Ridge
- MLDG: Mesio-lingual Developmental Groove
- CL: Cervical Line
- BCR: Buccal Cervical Ridge
- MCA: Mesial Contact Area
- MMR: Mesial Marginal Ridge
- MBCR: Mesobuccal Cusp Ridge
- DBCR: Distobuccal Cusp Ridge
- CDG: Central Developmental Groove
- DMR: Distal Marginal Ridge

MEASUREMENT TABLE

(in millimeters)

MANDIBULAR FIRST PREMOLAR		MANDIBULAR SECOND PREMOLAR	
Cervicoocclusal Length of Crown	8.5*	Cervicoocclusal Length of Crown	8.0*
Length of Root	14.0	Length of Root	14.5

Mesiodistal Diameter of Crown At Cervix	5.0	Mesiodistal Diameter of Crown At Cervix	5.0
Labio-buccolingual Diameter of Crown	7.5	Labio-Obuccolingual Diameter At Cervix	8.0
Labio-obucco-lingual Diameter of Crown at Cervix	6.5	Labio-Obucco Lingual Diameter At Cervix	7.0
Curvature of Cervical Line Mesial	1.0	Curvature of Cervical Line Mesial	1.0
Curvature of Cervical Line Distal	0.0	Curvature of Cervical Line Distal	0.0

GENERAL OUTSTANDING DIFFERENCES

MANDIBULAR FIRST PREMOLAR

- Crown does not show any variations
- Crown is smaller. The tooth is smallest of all premolars
- Less efficient as masticatory organ

MANDIBULAR SECOND PREMOLAR

- There are three types of Crowns Y, H and U
- Crown is larger. The tooth is largest of all premolars
- More efficient as masticatory organ

CHRONOLOGY

MANDIBULAR FIRST PREMOLAR		MANDIBULAR SECOND PREMOLAR	
First evidence of calcification	14 to 2 yr	First evidence of calcification	24 to 26 yr
Enamel completed	5 to 6 yr	Enamel completed	6 to 7 yr
Eruption	10 to 13 yr	Eruption	11 to 12 yr
Root Completed	12 to 13 yr	Root Completed	13 to 14 yr

THE CROWN : BUCCAL SURFACE

MANDIBULAR FIRST PREMOLAR

- Narrower Mesio-distally.
- Compared to its size occlusogingival length is not so short.
- Tip of the buccal cusp is sharper.
- Buccal developmental grooves well defined.
- Crown is bilaterally asymmetrical

MANDIBULAR SECOND PREMOLAR

- Wider Mesio-distally
- Occlusogingival length is shorter than other premolars.
- Tip of buccal cusp is not so sharp.
- Buccal developmental grooves are less defined
- Crown is bilaterally symmetrical

MESIAL AND DISTAL SURFACE (Cont.)

MANDIBULAR FIRST PREMOLAR

Mesial Distal

MANDIBULAR SECOND PREMOLAR

Mesial Distal

THE CROWN BUCCAL SURFACE (Cont.)

LINGUAL SURFACE (Cont.)

LINGUAL SURFACE

MANDIBULAR FIRST PREMOLAR

- Lingual surface is not so well developed and is much smaller.
- Lingual cusp is shorter and covers smaller area of the occlusal surface
- Lingual grooves is absent
- Mesio-lingual groove is present
- Surface does not show variation in size.

MANDIBULAR SECOND PREMOLAR

- Lingual surface is well developed and larger.
- Lingual cusp is bigger and covers larger area of occlusal surface.
- Lingual grooves is present in Y type.
- Surface show considerable variations may be narrower in width or same in width as buccal.

OCCLUSAL SURFACE

MANDIBULAR FIRST PREMOLAR

- Occlusal surface show no variation in the form.
- Smaller in size and masticatory function is less.
- Formed almost entirely by buccal cusp.
- Occlusal outline is diamond shape.
- Buccal cusp is more than twice the size of lingual cusp.
- Occlusal surface slopes lingually.
- Central pit is never present.
- Mesial marginal ridge is shorter and less prominent than distal marginal ridge.
- Transverse ridge is common linking occlusal & lingual cusps.

MANDIBULAR SECOND PREMOLAR

- Occlusal surface shows variation in the form. There are three types, Y, H and U type of occlusal
- Larger in size and masticatory function is more
- Formed by both buccal and lingual cusp.
- Occlusal outline is square of round.
- Buccal cusp is almost equal in size of lingual cusp
- Occlusal surface is horizontal.
- Central pit is present in Y type of premolar.
- Mesial and distal marginal ridge are similar.
- No transverse ridge is seen.

MESIAL AND DISTAL SURFACE

FIRST PREMOLAR

- Marginal grooves are usually absent
- Both mesial and distal surfaces are smaller.
- Mesial and distal surfaces converge more rapidly toward lingual
- Mesial marginal ridge inclines cervically above 45 degree.
- Mesio-lingual groove is present

SECOND PREMOLAR

- Marginal grooves are always present.
- Both mesial and distal surfaces are larger
- Mesial and distal surface converge less rapidly.
- Mesial marginal ridge is horizontal.
- No Mesio-lingual groove is present

OCCLUSAL SURFACE (Cont.)

THE ROOT

MANDIBULAR FIRST PREMOLAR

- Smaller in all dimensions.
- Usually straight.
- Root may show tendency to bifurcate.

MANDIBULAR SECOND PREMOLAR

- Larger in all dimensions.
- May tend to curve distally at apex.
- Root does not show tendency to bifurcate

DIFFERENCE BETWEEN PERMANENT MAXILLARY CENTRAL AND LATERAL INCISORS

GENERAL INTRODUCTION:

- The incisors are shearing or cutting teeth. > Their function is to punch and cut food material during process of mastication.
- Central Incisor is the largest incisor.

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> Crown is larger than root. The mesiodistal angle of crown is more but distobuccal angle is slightly curved. Labial aspect shows less curvature than lateral incisor. Tooth is relatively wider mesiodistally. 	<ul style="list-style-type: none"> Crown is smaller than root. The mesiodistal angle is slightly curved and the distobuccal angle is more curved compared to that of central incisor. More curvature than Central Incisor. Tooth is relatively narrower mesiodistally.

PERMANENT MAXILLARY CENTRAL INCISOR	PERMANENT MAXILLARY LATERAL INCISOR
<ul style="list-style-type: none"> 3-4 yrs eruption of calcification 2-4 months 30% completed 4.5 yrs 30% eruption 7-8 yrs 90% completed 10 yrs 	<ul style="list-style-type: none"> 3-4 yrs eruption of calcification 30-43 months 20% completed 4.5 yrs 80% eruption 8-9 yrs 90% completed 10 yrs

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> The Root of these is more curved and distobuccal than that found on central incisor. Incisor shows V shaped. The distobuccal groove is less pronounced than that found on the lateral incisor. Specifically the labial form of maxillary incisor incisor is more lingual. Upper & distal marginal ridges are less marked than lateral incisors. Diagonal is less pronounced compared to lateral incisor. 	<ul style="list-style-type: none"> The Root of these is more curved & distobuccal than that found on central incisor. Incisor shows V shaped. More distobuccal groove are visible on lingual side. Specifically the surface form of maxillary lateral incisor is less straight with respect to central incisor. Upper & distal marginal ridges are more marked than central incisor. Diagonal is more pronounced.

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> The cervical curvature is greater on mesial surface of central incisor compared to lateral incisors. All maxillary central incisors exhibit less curvature labially & lingually from incisal aspect than that of maxillary central incisors. 	<ul style="list-style-type: none"> The cervical curvature is less on the mesial surface of lateral incisors compared to that of Central incisors. All maxillary lateral incisors exhibit more curvature labially & lingually from incisal aspect than that of maxillary central incisors.

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> Crown is longer than root is relatively shorter than lateral. The mesial portion of tooth from mesial aspect appears rounded whereas the that of lateral incisor. Extent of curvature of cervical line more than that found in lateral incisors. 	<ul style="list-style-type: none"> Crown is shorter, root is relatively longer than lateral. The distal portion appears somewhat shorter than that of Central incisors. Extent of curvature of cervical line is less than that found on central incisors.

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> Root appears straight from distal aspect. See the short apex. 	<ul style="list-style-type: none"> Root appears slightly bulged from distal aspect. See the tapered apex.

CENTRAL INCISORS	LATERAL INCISORS
<ul style="list-style-type: none"> Distal surface of Central incisor from labial surface tends to be straight. Crown is somewhat straight, uncurved distal end. The Cervico-Enamel Junction Curvature is little more than Central incisors. 	<ul style="list-style-type: none"> Distal surface is more rounded, curve of curvature is more curved, usually in centre of middle 1/3. Crown is twisted, presents marginal ridge to labial face. The Cervico-Enamel Junction Curvature is little more than Central incisors.

PERMANENT MANDIBULAR FIRST MOLAR

INTRODUCTION

- Also known as "6 years molar"
- Largest tooth in mandibular arch.
- Mesiodistal dimension is larger than Bucco-lingual dimension.

MEASUREMENT TABLE

	Crown-occlusal length of crown	Length of Root	Mesiodistal diameter of crown	Mesiodistal diameter of crown at cervix	Bucco-lingual diameter of crown	Bucco-lingual diameter of crown at cervix	Cervical diameter of crown at cervix
Dimension in mm	7.5	14.0	11.0	9.0	10.5	8.0	5.8

CHRONOLOGY

First evidence of calcification	At Birth
Crown completed	2.5-3 years
Eruption	6-7 years
Root Completed	9-10 years

BUCCAL ASPECT

- It appears trapezoidal in shape.
- Mesiobuccal cusp > Distobuccal cusp > Distal aspect dimension.
- Distobuccal cusp is sharper.
- There are 2 Grooves on buccal surface:
 - Mesiobuccal groove
 - Distobuccal groove

- Buccal pit is more prominent on end of mesiobuccal groove.
- Mesial border: It follows convex to Middle third and then becomes straight upto cervical line.
- Contact area is at junction of occlusal and middle third.
- Distal border: convex and contact area at middle third.
- Roots: There are 2 roots, i.e. mesial and distal roots.

OCCUSAL ASPECT

- Crown appears hexagonal in shape.
- 5 cusps can be seen.
- The size of cusps in decreasing order is as follows - MB>ML>DL>DB>DISTAL.
- Ridges - 5 Triangular ridges
- 2 Marginal ridges.
- Size of mesial marginal ridges is greater than distal marginal ridge.
- Fossae - central fossa
- mesial triangular fossa
- distal triangular fossa

LINGUAL ASPECT

- From lingual aspect 3 cusp can be seen i.e. Mesiolingual, which is largest in size, then distolingual and then distal cusp.
- Width of mesiolingual and distolingual cusps are same.
- Root trunk is 4 mm long.
- Root appears longer.

MESIAL ASPECT

- Mesial marginal ridge is higher.
- Rhomboidal shape can be seen.

ROOTS:-

- Root is broad bucco-lingually.
- Mesial root have 2 root canals.
- Deep developmental depression can be seen.

DISTAL ASPECT

- 3 cusps are seen from distal aspect.
- Tooth is slightly tilted distally, so occlusal and mesial cusp can be seen.
- Distal marginal ridge is lower in height.
- Crown is narrowed distally.

Prepared By :- Kavan Doshi, Nilesh Gadiya, Dharti Gajjar, Dhaval Gohel, Poojan Dabhi . (First Year B.D.S)
Guided By :- Department of Oral Pathology and Microbiology .
 Batch: 2014-2015

Mandibular Second Molar

Introduction-

- The mandibular second molar supplements first molar in function.
- The crown has 4 well developed cusps 2 buccal & 2 lingual & 2 roots (1 mesial & 1 distal).
- Second molar is smaller than first.

Chronology-

1 st evidence of calcification	: 2-3 year
Enamel completed	: 7-8 year
Eruption	: 11-13 year
Root completed	: 14-15 year

Buccal Aspect-

- Buccal crown is shorter cervico-occlusally and narrower mesiodistally than 1st molar.
- Development groove lies buccally – the buccal developmental groove.
- The cervical line buccally points sharply towards the root bifurcation.
- The roots are inclined distally in relation to the occlusal plane of the crown.

Occlusal Aspect-

- Distobuccal lobe is more pronounced than mesiobuccal lobe.
- Buccal and lingual developmental grooves meet the central developmental groove at right angles.
- These grooves form 4 cusps.
- Cusp slopes on occlusal surface are not smooth as on 1st molars because they are roughened by many supplemental groove radiating from the developmental groove.

Lingual Aspect-

- The crown and root converge lingually due to this little mesial and distal surface can be seen.
- This mesiodistal calibration at the cervix lingually is always greater than 1st molar.
- Curvatures mesially and distally on crown are noticeable from these aspect.

Mesial Aspect-

- Mesial marginal ridge is 'V' shaped.
- Occlusal surface is more constricted bucco-lingually.
- Cervical line shows less curvature.
- Mesial root is pointed apically.
- Distally root may be seen buccally.

Distal Aspect-

- There is absence of distal cusp and distobuccal groove.
- Contact area is centered on distal surface.

Cervico occlusal length	Length of root	Mesiodistal diameter of the crown	Mesiodistal diameter of crown at cervix	Labial diameter of crown	Labio diameter of crown at cervix
7.0 mm	13.0 mm	10.5 mm	8.0 mm	10.0 mm	9.0 mm

MAXILLARY SINUS (Antrum of Highmore)

Sinus are air filled spaces within bone.

Maxillary sinus is pneumatic space inside the body of maxilla that communicates with environment by means of middle nasal meatus and nasal vestibule.

It's largest of all sinuses. It has its opening on the posterior part of Hiatus semilunaris

DEVELOPMENT

- Maxillary sinus is the first sinus to develop.
- It appears as shallow groove on medial surface of maxilla during 16th week/4th month of intrauterine life
- It grows rapidly for 6-7 years.
- The cavity develops laterally and downward thus have ostium at upper and other recesses.

FUNCTIONS

- Being an air space, it lessens the weight of skull
- Provides voice resonance
- Protects skull against mechanical shock
- It warms & moistens the inspired air.
- It produces bactericidal lysozyme & contribute to defence against bacterial infection.

STRUCTURE

It's described as a 4 sided pyramid. Base is located medially and the apex is located laterally.

The 4 sides of pyramid is as follows -

Anterior : To facial surface of body

Posterior : To infraorbital surface

Superior : To orbital surface

Inferior : To alveolar & zygomatic process

Base of sinus is it's thinnest wall with perforation in it called as ostium

MICROSCOPIC FEATURES

- 3 layers are seen: 1. Epithelial layer 2. Basal layer 3. Sub-epithelial layer
- Epithelium is made of pseudostratified ciliated columnar derived from olfactory epithelium of middle nasal meatus.
- Most common cells found are columnar ciliated. Other cells are also found they are - Basal cells, columnar non-ciliated, mucous secreting goblet cell.
- The goblet cells displays all the characteristics of secretory cells.
- On the basis of histochemical differentiation it's evident that acini of subepithelial glands contains two types of cells-serous & mucous
- The secretion of this glands is controlled by both divisions of ANS
- They autonomic axon, together with general sensory components are supplied to maxillary sinus from maxillary sinus complex.
- Numerous myelinated & non-myelinated axons are present in subepithelial layer of sinus. They are related here to blood capillaries, fibroblasts, fibrocytes, collagen bundle & other connective tissue elements.

ANATOMICAL LANDMARKS OF TOOTH

CUSP:

→ An elevation or mound on the crown portion of a tooth making up a divisional part of the occlusal surface.

TUBERCLE:

→ is a smaller elevation on some portion of the crown produced by an extra formation of enamel. Deviation from the typical form are evident.

CINGULUM:

→ is the lingual lobe of an anterior tooth & makes up the bulk of the cervical third of the lingual surface. Its convexity resembles a girdle encircling the lingual surface.

RIDGE:

→ Are any linear elevation on the surface of a tooth & is named according to its location.

MARGINAL RIDGE:

→ are those rounded border of the enamel that form the mesial & distal margins of the occlusal surface of the premolar & molar and mesial & distal margins of the lingual surface of the incisor & canine.

TRIANGULAR RIDGE:

→ descend from the tips of the cusps of molars & premolar toward the central part of the occlusal surfaces.

Triangular Ridge

OBLIQUE RIDGE:

→ is a ridge obliquely crossing the occlusal surfaces of maxillary molars & formed by the union of the triangular ridge of the distobuccal cusp & the distal cusp of the mesiolingual cusp.

FOSSA:

→ is an irregular depression or concavity.

SULCUS:

→ is a long depression or valley in the surface of a tooth between ridges & cusps' the inclines of which meet at an angle.

TRANSVERSE RIDGE:

→ is the union of two triangular ridges transversely crossing the surface of a posterior teeth.

DEVELOPMENTAL GROOVE:

→ a shallow groove or line between the primary parts of the crown root.

Developmental groove

SUPPLEMENTAL GROOVE:

→ is less distinct is also a shallow linear depression on the surface of a tooth but is supplemental to developmental groove and does not mark the junction of primary parts.

PITS:

→ are small pinpoint depression located at the junction of developmental grooves or at the terminals of those grooves.

LOBE:

→ is one of the primary sections of formation in the development of the crown. Cusps and mamelons are representative of lobes.

MAMELON:

→ is any one of the three rounded protuberances found on the incisal ridges of newly erupted incisor teeth.

PERMANENT MANDIBULAR RIGHT CENTRAL INCISOR

INTRODUCTION:-

- The mandibular incisors have smaller mesiodistal dimensions than any of the other teeth.
- These teeth have smooth crown surfaces that show few traces of development lines.
- The crown has little more than half the mesiodistal diameter of the maxillary central incisor.

CHRONOLOGY:-

- First evidence of calcification :3 to 4 months
- Enamel completed :4 to 5 years
- Eruption :6 to 7 years
- Root completed :9 years

MEASUREMENT TABLE :-

Cervical Incisal Length Of Crown	Length Of Root	Mesiodistal Diameter Of Crown	Mesiodistal Diameter Of Crown At Cervix	Labial-Or Bucco-Lingual Diameter Of crown	Labial-Or Bucco-Lingual Diameter Of crown At Cervix	Curvature Of Cervical Line-Mesial	Curvature Of Cervical Line-Distal
9.5	12.5	5.0	3.5	6.0	5.3	3.0	2.0

LABIAL ASPECT :-

- It is regular, tapering evenly from mesial and distal incisal angles to the apical portion of the root.
- The incisal ridge of the crown is straight and at right angle to the long axis of the tooth.
- The mesial and distal sides of the crown taper evenly from the contact areas to the narrow cervix.
- The apical third of the root terminates in a small, pointed taper curving distally.
- The crown is ordinarily smooth at the incisal third; the middle third is more convex, narrowing down to the convexity of the root at the cervical portion.

LINGUAL ASPECT :-

- The crown is smooth with slight concavity at the incisal third.
- The lingual surface becomes flat and then convex from the incisal third to cervical third.
- No developmental lines mark the gingulum development at the cervical third.
- The outlines and surfaces are regular and symmetrical.

MESIAL ASPECT :-

- The outline of the labial face of the crown is straight.
- The incisal ridge is rounded.
- The curvature of the cervical line representing the cementsoenamel junction (CEJ) curves incisally.
- The roots have broad developmental depression at the junction of the middle and apical thirds.

DISTAL ASPECT :-

- The cervical line representing the cementsoenamel junction (CEJ) curves incisally about 1 mm less than on the mesial.
- The distal surface is similar to that of the mesial surface.
- The developmental depression has a well defined developmental groove at its center.

INCISAL ASPECT :-

- The incisal edge is at right angles to the line bisecting the crown labiolingually. This feature is characteristic of the tooth and serves as a mark of identification in differentiation between mandibular central and lateral incisors.
- The labiolingual diameter is always greater.
- The labial surface of the crown is wider mesiodistally than the lingual surface.

ROOT :-

- The root is narrower, thinner and shorter.
- Longitudinal groove are less convex.
- Variation at root is not common.

Mandibular Central incisor	Mandibular Lateral Incisor
<ul style="list-style-type: none"> Incisal edge is straight and crown does not appear to be rotated on long axis. Labial profile is flat. Labial lobes does not visible. 	<ul style="list-style-type: none"> Incisal edge is inclined towards lingual as it goes from mesial to distal and crown appear to be rotated on long axis. Labial profile is rounded. Labial lobes are visible.

LABIAL ASPECT

Mandibular Central Incisor	Mandibular Lateral Incisor
<ul style="list-style-type: none"> Labial surface is narrower Mesio-distally In the Mesio-distal direction the incisal portion is less Convex. Mesial and distal border are equal in length. Incisal border is at right angle to the long axis to the tooth. Mesio-incisal and disto-incisal angle are almost at right angle. Mesio and distal lobes are approximately equal in length, width and degree of prominence. Mamelons : Mesial and distal mamelons are equally prominent. 	<ul style="list-style-type: none"> Labial surface is wider Mesio-distally. In the Mesio-distal direction the incisal portion is more convex. Distal border is shorter than Mesial. Incisal border shows inclination towards cervical as it extends from mesial to distal. Mesio-incisal is almost at right angle while disto-incisal angle is rounded. Mesial lobe is longer and more prominent than distal lobe. Mamelons : Distal mamelons are less prominent.

ROOT ASPECT

Mandibular Central Incisor	Mandibular Lateral Incisor
<ul style="list-style-type: none"> The root is narrow, thinner, shorter. Longitudinal grooves are less common. The root is always straight. 	<ul style="list-style-type: none"> The root is wider, thicker, little longer. Longitudinal grooves are more common. The root is usually straight.

MAXILLARY LATERAL INCISOR

Introduction :

The lateral incisor is smaller in all dimensions except the root length. This tooth differs from Central Incisor in its development which may vary considerably. A common situation is to find MLJ with a non-descript pointed form such teeth are called peg-shaped laterals. The presence of Palato-Radiolar groove in MI may be a predisposing factor in periodontal disease. This groove is also known as Palato-Radiolar groove.

CHRONOLOGY:

First evidence of calcification : 1 year
 Enamel completed : 4 to 5 years
 Eruption : 8 to 9 years
 Root completed : 11 years

CERVICO-INCISAL LENGTH OF CROWN	LENGTH OF ROOT	MESIODISTAL DIAMETER OF CROWN	MESIOBISTAL DIAMETER OF CROWN AT CERVIX	LABIO-OR-BUCCO LINGUAL DIAMETER OF CROWN	LABIO-OR-BUCCO LINGUAL DIAMETER AT CERVIX
9.6	13.0	8.5	9.0	4.0	5.0

LABIAL ASPECT:

- Maxillary Lateral Incisor usually has more curvatures with a rounded Incisal Ridge and rounded incisal angles mesially and distally.
- The distal outline is always more rounded, & the crest of contour is more cervical.
- The labial surface of the Crown is more convex.
- The crown measures from 2-3mm shorter Cervico-incisally than that of CI.
- The Root usually somewhat as long as that of CI.
- The root length is greater in proportion to its crown length than that of CI.
- The root is often about 1.5 times the length of crown.

MESIAL ASPECT:

- The Crown is shorter, the Root is relatively longer.
- The labiolingual measurement of crown and root is millimeter or so less than CI.
- Curvature of the cervical line is marked in the direction of incisal ridge, the actual extent of curvature is less than that found in the CI.
- Incisal portion is somewhat thicker because of the development of the mesial ridge.
- The root appears as a tapered cone from this aspect with a bluntly rounded apical end.
- The labial outline of root is straight from this aspect.

INCISAL ASPECT:

- The tooth conforms in its development to its CI in other aspects, except the size. However, the Cingulum may be large as in the Incisal Ridge.
- Additionally the Labiolingual dimension may be greater than usual in comparison with the mesiodistal dimension.
- If these variations are present the tooth has a mark resemblance to a small canine.

LINGUAL ASPECT:

- The cingulum is usually prominent with a tendency towards deep developmental grooves within the lingual fossa.
- The linguoincisor ridge is well developed and the lingual fossae more concave.
- The tooth tapers towards the lingual.

DISTAL ASPECT:

- The width of the Crown distally appears thicker than it does on the Mesial Aspect from marginal ridge to labial face.
- The curvature of Cervical line is usually a mm or less in depth than on the Mesial side.
- It is not uncommon to find a developmental groove distally on this crown extending on the root for part or all of its length.

SALIVA – Formation, Composition and Functions

Saliva is a complex fluid produced by the salivary glands, the most important function of saliva is to maintain the well being of the mouth.

FORMATION OF SALIVA

Saliva is formed in the secretory end piece and is made of 2 components

Fluid and electrolytes

- Secretion of water is regulated by parasympathetic innervation.
- ACh/Norepinephrine/Subs.P binds to receptors & activates Phospholipase C
- Release of Ca^{2+} from intracellular stores
- Cl^- channels (Cl^- efflux)
- Na^+ channels (Na^+ influx)
- Change in osmotic gradient
- Flow of water into the lumen

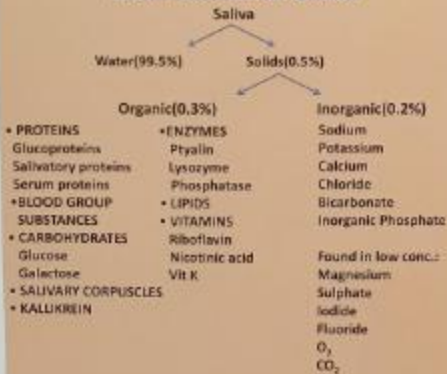

Macromolecular components

- Nucleus of cell send message (mRNA) to ribosomes
- Signal sequence synthesized & attached to RER membrane
- RER vesicles reach cis face of Golgi apparatus(GA)
- Vesicles migrate to trans face of GA where they are packed into vacuoles (immature granules)
- Granules undergo glycosylation
- Mature granules stored at the apex of the cell
- Granules are emptied by exocytosis (serous cells)
- Mucous droplets (mucous cells)

Control of secretion is mediated by ANS (parasympathetic). For control of secretion gustatory stimulus is more important than masticatory stimulus.

COMPOSITION OF SALIVA

FUNCTIONS OF SALIVA

- ◊CLEANSING: Flushes away debris and non adherent bacteria.
- ◊LUBRICATION & MUCOSAL INTEGRITY: Presence of Mucin and Glycoproteins lubricates. OMM.
- ◊BUFFERING: Primary system made by Bicarbonates.
- ◊REMNERALIZATION: Formation of Enamel Pellicle prevents caries.
- ◊ANTIMICROBIAL: Due to presence of Lysozymes, Lactoferrins, Immunoglobulins.
- ◊FORMATION OF BOLUS: Helps in Deglutition & Mastication.
- ◊SPEECH: Helps in vocalization and communication.
- ◊TASTE PERCEPTION: Maintained by presence of Water and Lipocalins.
- ◊DIGESTION: If participates by presence of Salivary Amylase and Lingual Lipase.
- ◊BLOOD CLOTTING: Includes Vitamin K, Kallikrein, and Nerve Growth Factor.

GIANT CELL LESIONS

Giant cell: Giant cells are large (40-50µ) multinucleated cells, formed by fusion of macrophage with only occasional internal nuclear division.

CLASSIFICATION

MICROBIAL LESION	TUMOR AND TUMOR LIKE LESION	CYSTIC LESION	BONY LESION	METABOLIC LESION
1) Tuberculosis 2) Leprosy 3) Actinomycosis 4) Sarcoidosis	1) Central giant cell 2) Peripheral 3) Giant cell fibroma 4) Giant cell tumor 5) Osteosarcoma 6) Rhabdomyosarcoma 7) Hodgkin's lymphoma	1) Traumatic cyst 2) Aneurysmal bone cyst	1) Cherubism 2) Paget's disease 3) Fibrous dysplasia	1) Hyperparathyroidism

TYPES

FOREIGN BODY	LANGHAN'S	TOUTON	TUMOR	MISCELLANEOUS
<ul style="list-style-type: none"> ➤ Nuclei (up to 100µ) which are uniform in size & shape and resembles the nuclei of macrophages. ➤ Seen in chronic infective granulomas, Leprosy & TB. 	<ul style="list-style-type: none"> ➤ Nuclei resembles macrophages and epithelioid cell. These nuclei are arranged around the periphery in the form of horseshoe shape or ring or clustered at the 2 poles of giant cells. ➤ Seen in TB and sarcoidosis. 	<ul style="list-style-type: none"> ➤ There are multinucleated cells which have vacuolated cytoplasm due to lipid content. ➤ e.g. Ixodanthoma 	<ul style="list-style-type: none"> ➤ Nuclei are hyperchromatic and vary in size and shape. ➤ e.g. In carcinoma of liver and various soft tissue sarcoma. 	<ul style="list-style-type: none"> ➤ These includes presence of numerous nuclei in mesodermal cells. ➤ e.g. Aschoff cells of rheumatic nodule, Reed-Sternberg cells of Hodgkin's disease and osteoclast like cells.

CENTRAL GIANT CELL GRANULOMA

Uncommon, benign & proliferative lesion.

CLINICAL FEATURES:

- Common in young ones especially <30 years of age.
- Female > Male
- Mandible > Maxilla
- Common in anterior segment of jaws
- Expansion of cortex & perforation.
- Mobility, displacement and root resorption of associated teeth.
- Classified in to 1) Aggressive
- 2) Non-Aggressive

HISTOLOGIC FEATURE:

- Loose fibrillar connective tissue stroma with proliferating fibroblasts & small capillaries.
- Multinucleated giant cells in CT which are osteoclast like & formed from monocyte or macrophage.

RADIOLOGIC FEATURES

- Multilocular radiolucency.

TREATMENT:

- Curettage or surgical excision

PERIPHERAL GIANT CELL GRANULOMA

Reactive & Non specific nodular mass of growth present on gingiva.

CLINICAL FEATURE:

- 4th-6th decade of life
- Female > Male
- Mandible > Maxilla
- Anterior > Molars
- Asymptomatic and about 1cm in size
- Pedunculated or sessile lesion often dark red vascular or haemorrhagic in appearance.

HISTOLOGIC FEATURE:

- Characteristic feature - Zone of dense fibrous CT separating the lesion from overlying stratified squamous epithelium.
- Multinucleated giant cells are distributed in highly cellular CT having numerous spindle shape resembling osteoclast being round.

RADIOLOGIC FEATURES:

- Peripheral cuffing of bone.

TREATMENT:

- Curettage

GIANT CELL TUMOR OF BONE

It is distinctive neoplasm of undifferentiated cells.

CLINICAL FEATURES:

- Seen in >19yr with a peak incidence in the 3rd decade of life.
- Female > Male
- Swelling on affected region
- Weakness and limitation of motion of jaw

HISTOLOGIC FEATURE:

- Basic proliferating cells has round to oval or even spindle shaped nucleus in the field that is diagnosis of true giant cell tumor.
- Nucleus is surrounded by ill defined cytoplasm.
- Inter cellular substance is absent.
- Mitotic figures can be found.
- Areas of infarct like necrosis is common.

TREATMENT:

- Curettage
- Cryosurgery

ANEMIA

Anemia is defined as an abnormal reduction in number of circulating Red blood cells, the quantity of haemoglobin and volume of packed red cell in given unit of blood

Classification

According to pathophysiology

Anemia due to altered blood loss

Acute post-hemorrhagic anemia

Chronic blood loss

Anemia due to impaired RBC production

Cytopenia (involvement of other cells)

Bone marrow aplasia

Defect in stem cell proliferation and differentiation

According to morphology

Normocytic, Microcytic

Hypochromic, Microcytic

Hypochromic, Macrocytic

Normocytic, Normochromic

Anemia of chronic disorders

Nuclear maturation defects

Congenital anemia

Vitamin B12 and/or folic acid deficiency

Megaloblastic anemia

- Defect in hem synthesis - Iron deficiency anemia
- Defect in globin synthesis - Thalassemia syndromes

- Aplastic Anemia
- Pure red cell aplasia

IRON DEFICIENCY ANEMIA

The iron deficiency arises through chronic blood loss, inadequate dietary intake, faulty iron absorption or because of increased requirement or iron.

Associated with PLUMMER-VINCOU SYNDROME

ORAL MANIFESTATIONS

- Glossitis and stomatitis
- Angular cheilitis
- Atrophy of tongue and lid film pallor
- Pale oral mucosa
- Candidiasis
- Stomatitis minoris
- Dentition
- Burning sensation in mouth

SICKLE CELL ANEMIA

Pinhead microscopic appearance of sickle shaped erythrocytes found in circulating blood. The normal adult Hb (HbA1) is generally altered to produce sickle Hb (HbS).

ORAL MANIFESTATIONS

- Significant bone changes in dental radiograph - MGJ to mandible
- Retroposition and a loss of calcification of jaw bones with appearance of large irregular marrow spaces
- Nasal enlargement, to nasal bridge and at medial maxillary tuberosity

PERNICIOUS ANEMIA (Addison-Biermer anemia)

Vitamin B12 deficiency - It develops because of loss of gastric parietal cells, which are responsible for secretion of intrinsic factor

ORAL MANIFESTATION

- Glossitis, painful and burning in oral mucosa
- Angular cheilitis
- Tongue - beefy red color
- Stomatitis - resembling atrophic stomatitis - atrophic or tongue
- Atrophy of epithelium - bald tongue
- Loss of taste sensation
- Burning sensation
- The burning sensation extends to involve the entire oral mucosa

APLASTIC ANEMIA

It is a bone marrow failure syndrome characterized by pancytopenia and general lack of bone marrow activity. PANCYTOPENIA: It may affect RBC, WBC and platelets resulting in pancytopenia

ORAL MANIFESTATIONS

- Retention of purpuric spots or frank hemorrhages of the oral mucosa may occur at any site, while haemorrhage into the oral cavity
- Development of ulcerative lesions of the oral mucosa or pharynx

THALASSEMIA (Cooley's Anemia, Erythroblastic Anemia, Mediterranean Anemia)

Genetically determined disorders of Hb synthesis with decreased production of either alpha or beta polypeptide chains of haemoglobin molecules

3 types: Thalassemia Major and Thalassemia Minor

ORAL MANIFESTATION

- Prominent Stomatitis results in an obvious malocclusion
- Oral mucosa exhibits anemia pallor, ulcers
